Leave and Passages.—Leave of absence in East Africa on full salary is granted in the normal case after a tour of residential service (of not less than 20 and not usually more than 30 months) to an amount of six days for each completed month of residence (or three days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro, for which full pay is also given. Officers serving in certain stations in Kenya and Nyasaland are allowed five (or two and a half) days' leave and in Northern Rhodesia four (or two) days' leave in respect of each month of service instead of six (or three) days' leave respectively. In Somaliland special leave regulations exist which provide for an officer taking leave after a shorter tour of service than in other parts of East Africa. Free first-class passages are provided for the officer on first appointment and on leave, and in certain cases assistance towards family passages is given.

In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half-pay may be granted on special grounds. Up to the end of 1928 free passages are granted on first appointment and on leave, and free passages on first appointment or transfer are granted permanently for officers with salary under £800.

In other Colonies outside Tropical Africa, subject to the necessities of the service, leave of absence on half salary may be granted after a period of three years' resident service without any special grounds. It may be given before the expiration of that period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months[4] in any two years. In British Guiana assisted passages are granted to officers proceeding on leave. British Guiana, Jamaica, and Trinidad officers are allowed to accumulate full-pay leave at the rate of six weeks for each year's service up to six months, exclusive of the period of the voyages to and fro, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay may be taken in addition to six months' full-pay leave.

On first appointment an officer will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. An officer taking leave out of the Colony has in most cases to provide his own passages.

Pensions.—East Africa.—Officers on the pensionable establishment retire on attaining the age of 50 years; but they may be retained in the service, with their own consent, for such further period as the Government may recommend. Earlier retirement in the event of ill-health is also provided for. Pension is computed at one-four hundred and eightieth of pensionable emoluments—i.e., salary and value of free quarters[5] in respect of each month's pensiona service—at the time of retirement, subject to average of emoluments for the last three years bef retirement instead of the actual emoluments at time of retirement being taken as the basis calculation in certain circumstances.

Other Colonies.—In most of the other Colonies officer holding a pensionable appointment may allowed in the case of ill-health to retire on a pens after ten full years' resident service; otherwise must have attained the age of 55. For ten full yea resident service fifteen-sixtieths of the average ann salary of the retiring officer's fixed appointments three years prior to retirement may be awarded, which one-sixtieth may be added for each additio year's service; but no addition will be made in resp of any service beyond 35 years. For pension purpo absence on vacation leave counts as full service, a leave on half-pay as half service. In a few cases retiring age is 60 and the pension after ten yea service is ten-sixtieths instead of fifteen. In Straits Settlements and Malay States, an officer m with the consent of Government, retire at age Pensions are calculated on a basis of length of serv in months instead of years.

WEST AFRICAN MEDICAL STAFF.

Applicants for appointment as medical offic or medical officers of health in the West Afri Medical Staff (the higher grades will usually filled by promotion from the lower) must British subjects of European parentage and betw 23 and 35 years of age; preference is given to can dates who are over 25 years of age. Applicants m possess a complete double qualification, and must on the Medical Register. Passages for wives a children are not provided by the Government, houses for the wives of junior medical officers rarely available. Officers are not usually allowed take their wives and young children out with th until they have acquired experience of the lo conditions and have obtained the sanction of Governor. When an officer has obtained permiss to be accompanied by his wife a grant of one-half cost of his wife's passage to and from West Afric made subject to certain conditions.

Candidates whom it is proposed to select appointment will have to be medically examined one of the medical advisers of the Colonial Office in the case of those residing in a Colony, by a medi officer appointed by the Colonial Government), no appointment will be made unless the candidat declared to be physically fit for service in West Afr Candidates are allowed to express a preference any particular Colony or Protectorate, and th wishes in this respect will be borne in mind and as far as possible, but they are liable to be postec the first instance, or transferred afterwards if necess to any other West African Colony or Protectorate the discretion of the Secretary of State. Candida who wish to be posted to Nigeria will probably fin useful to be able to ride. Transfers from Colony or Protectorate to another will be made seldom as possible. Candidates should on no acco apply for, or accept, a West African appointm in the expectation of ultimately being transferred.

Those transferred to pensionable Crown appoi ments elsewhere than in West Africa do not for their claim to pension in respect of their West Afri service on final retirement, provided that they h been members of the staff for at least 12 mon Every officer selected for appointment is required have himself revaccinated before proceeding to W Africa, unless one of the medical advisers of Colonial Office certifies that this is unnecessary.

Instruction in Tropical Medicine.—Every candid selected for appointment will, unless the Secretar

[4] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years.

[5] The value of free quarters for pension purposes is take 15 per cent. of the minimum salary of the grade in whic officer is serving at the time of retirement, subject t maximum of £150.

e decides otherwise, be required to undergo a se of instruction either at the London School of iene and Tropical Medicine, Endsleigh-gardens, 7. 1, or at the Liverpool School of Tropical icine, University, Liverpool, or at Edinburgh versity. The cost of tuition will be borne he Government, but candidates must make their arrangements for board and lodging; an vance of £25 a month will be paid to them thly in arrear while they are under instruction, may be continued up to the date of embarkation. h candidate is required to sign an agreement er which he is bound to refund all sums issued as vances and the cost of tuition (1) if he declines to pt an appointment in any of the Colonies or Protectes for which he may be selected; (2) if he fails to in a certificate in regard to progress and efficiency; 3) if he relinquishes the Service for any other on than mental or physical infirmity, or is removed misconduct, within three years of his arrival in t Africa.

at the end of the session there exists no vacancy he Staff to which a candidate can be appointed, ill be placed in a Reserve and granted an allow- at the rate of £200 a year until the occurrence of cancy.

ave of Absence.—European officers in West ca may be granted vacation leave on full salary exceeding in all one week's leave in the United gdom for every completed calendar month of l residential service in West Africa, plus the time ssarily taken on the journey to the United gdom, and, if the officer is returning to West ca for further service, the time necessarily taken he journey from the United Kingdom to the ny. Vacation leave may be granted without any ial grounds after 18 consecutive calendar months of lential service in West Africa. An officer will be required to serve a tour of more than 24 ecutive calendar months' residential service pt in special circumstances; and the Governor grant vacation leave to any officer at any time he has completed 12 consecutive calendar ths' residential service. Vacation leave on full y may also be granted to an officer if he is invalided West Africa after less than 12 consecutive dar months' residential service, and sick leave ull salary may be granted for any period not eding six calendar months.

ppointments and Salaries.—Medical officers for West African Colonies and Protectorates—ely, the Gambia, Sierra Leone, the Gold Coast uding Ashanti and the Northern Territories), and ria (Southern and Northern Provinces)—are ted by the Secretary of State for the Colonies, are on one list for employment and promotion. grades and emoluments of the Staff are at present llows:—

e Director of the Medical and Sanitary Service, Nigeria, ves a salary of £1800 a year, with a duty allowance at rate of £360 a year. The Director of Medical and tary Service in the Gold Coast receives a salary of 0 a year, with a duty allowance at the rate of £320 a The Director of Medical and Sanitary Service in a Leone receives a salary of £1400 a year, with a duty ance at the rate of £280 a year. The Deputy tor of Medical and Sanitary Service, Nigeria, and the ty Director of Sanitary Service, Nigeria, receive salaries 500 a year, with duty allowances at the rate of £300 a The Deputy Director of Medical and Sanitary Service, Coast, and the Assistant Director of Medical and ary Services, Nigeria, receive salaries of £1400 a year, duty allowances at the rate of £280 a year. Assistant tors Medical Service: There are seven appointments is grade, five in Nigeria, two in the Gold Coast. The y is at the rate of £1300 a year, with duty allowance at ate of £260 a year. The Assistant Director of Sanitary ce, Nigeria, the Deputy Director of Sanitary Service in old Coast and the Deputy Director of Sanitary Service erra Leone receive salary at the rate of £1300 a year, duty allowance at the rate of £260 a year. Specialists: number of these appointments is not fixed, officers of anding professional merit being eligible for appointment. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. After five years' approved service as such, the specialist officer is eligible to receive a salary at the rate of £1400 a year, with duty allowance at the rate of £280 a year. There are at present five officers appointed specialists in Nigeria, three in the Gold Coast, and one in Sierra Leone. Senior Medical Officer: There are twenty appointments of this grade, with salary at the rate of £1000 a year, rising by annual increments of £50 to £1150 a year, and seniority allowance at the rate of £100 a year. The Senior Medical Officer, Gambia, is allowed "staff pay" of £150 a year, in addition to duty allowance, but he is debarred from private practice. Senior Sanitary Officer: There are nine appointments of this grade, with salary at the rate of £1050 a year, rising by annual increments of £50 to £1200 a year, and a duty allowance at the rate of £210 a year. Possession of the Diploma in Public Health is usually required for appointment to this grade. Special facilities are granted to study for the diploma during leave. Medical Officers of Health: There are at present 24 appointments of this grade. The salary scale is the same as that of Medical Officers, except that Medical Officers of Health are granted an initial salary at the rate of £800 a year, together with seniority allowance at the rate of £72 a year and staff pay at the rate of £150 a year, half of which is payable during leave. After three years' service on the maximum of the scale, viz., £960 a year, and on undergoing an approved course of study, Medical Officers of Health are eligible, if unpromoted, subject to the recommendation of the Governor, to be placed on the scale £1000 a year rising by annual increments of £50 to £1150 a year, together with seniority allowance at the rate of £100 a year and staff pay as before. The holders of these appointments are not allowed private practice. Candidates selected for service as Medical Officers of Health must obtain the Diploma in Tropical Medicine and Hygiene of Cambridge, London, or Liverpool as a condition of appointment, and are appointed subject to the condition that, if after a period of service in West Africa they are considered unsuitable to serve in that capacity, they may be called upon to transfer to the medical side. In such cases the officers are given the rate of salary which they would have reached if they had been appointed to be Medical Officers instead of Medical Officers of Health in the first instance. Medical Officer: The salary attached to this grade is at the rate of £660 a year, rising by annual increments of £30 to £720 a year. Then, if confirmed in the appointment, £720 a year, rising by annual increments of £40 to £960, with seniority allowance at the rate of £72 a year. Before passing £800, medical officers are required to take a special course of study for three months. If they obtain satisfactory certificates at the end of the course they draw their further increments up to £960 a year.

A medical officer who has served for three years on the maximum salary of this scale (£960) without obtaining promotion is eligible, if recommended by the Governor, to be placed on the scale £1000–£50–£1150, with £100 seniority allowance (as for Senior Medical Officers).

Special Appointments.—The Director of the Medical Research Institute, Lagos, and the Director of Research, Accra, receive a salary of £1300 a year, with a duty allowance of £260 a year, rising after five years' approved service to a salary at the rate of £1400 a year and duty allowance at the rate of £280 a year. There are a number of appointments for pathologists and bacteriologists in Nigeria and the Gold Coast. The salary and other conditions attached to these posts are similar to those of Medical Officers of Health. Duty allowances, seniority allowance, and staff pay are not pensionable emoluments.

Increments.—Increments to salaries are payable only when the service of an officer during the period of employment qualifying for increment is approved.

Payment of Salaries.—Information as to the payment of officers' salaries or of monthly remittances to persons in England may be obtained from the Crown Agents for the Colonies, 4, Millbank, S.W. 1. All allowances are paid locally.

All officers of the staff, except directors, deputy directors, assistant directors, senior sanitary officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the faithful and efficient performance of their official duties, but it is within the power of the Governor to withdraw

or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at the majority of stations, and no guarantee can be given that an officer will be posted to a station in which he will be able to practise privately. As a general rule, and subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the Staff.

Pensions and Gratuities.—Pensions and gratuities on retirement are granted in accordance with the law and regulations of each individual Colony.

Fuller information can be obtained from the Private Secretary, Colonial Office, 38, Old Queen-street, London, S.W.1.

SUDAN MEDICAL SERVICE.

This service is responsible for carrying out civil medical and public health duties in the Sudan. The staff consists of :—(*a*) A Director—pay £1500–£1800. (*b*) A Senior Physician and a Senior Surgeon to the Khartoum and Omdurman Civil Hospitals —pay £1200–£1750. (*c*) An Assistant Director and Medical Officer of Health, Khartoum Province—pay £1200. (This post is temporary and the terms and duties are subject to alteration.) (*d*) Twenty-eight "Senior Medical Inspectors" and "Medical Inspectors" who are all British. The pay of the Inspectors commences at £720, and rises, subject to the recommendation of the Director, by five biennial increases to £1080, and thence, after 13 years' service, to £1200. The Senior Medical Inspectors are eligible by selection to the four senior posts. All Medical Inspectors are appointed on probation for two years. If at the expiration of this time they are taken on the permanent service of the Government, the increase of pay is subject to passing such examination in Arabic as may be required by the regulations. (*e*) A number of medical officers trained at one of the Syrian medical schools. (*f*) A number of assistant medical officers, natives of the Sudan, who have been given a purely clinical training in one of the larger Sudan hospitals.

Among the attractions of the service are: *Annual leave* of 90 days for every year's service, which in ordinary circumstances is granted each year, *study-leave* for some definite purpose, and two years granted towards pension to those who have obtained special qualifications and experience. The pension for a medical inspector retiring after 20 years' service is, as a rule, not less than £500 a year. Private practice is limited to a few of the larger towns, but may be carried on so long as it does not in any way interfere with official duties. These duties include acting as consultant to the principal hospitals, and supervising smaller hospitals or dispensaries; initiating and supervising the medical and sanitary work of a province; the medical supervision of schools; the examination of candidates for Government service and pension; and the training of assistant medical officers and native sanitary overseers. In the Khartoum medical school there are opportunities for teaching; the Registrar receives £250 a year, and the other teachers receive remuneration in addition to their pay. The country is developing rapidly and the Medical Department is being enlarged to meet the increased requirements of the service.

Four additional medical inspectors have recently been appointed, bringing the total number up to 28, and there will be further vacancies next year, which will be advertised in THE LANCET as they arise. Candidates must be single, under 30 years of age, and they must have held a resident post, preferably house surgeon, in a large general hospital. They may be required to take out a course of Tropical Medicine in this country before leaving; the fees, in addition to an allowance of £4 15*s.* per week during this period, will be paid by the Sudan Government.

Applications for further information should be made to Dr. T. Dyke Acland, 19, Bryanston-square, W., or to the Deans of the principal medical schools.

WOMEN'S MEDICAL SERVICE FOR IND

AMONG careers open to medical women abroad Women's Medical Service for India deserves hon able mention. This service is open to f qualified medical women of British or In nationality, and with the present amount of Gov ment subsidy the number of medical officers limited to 44. Medical women proceeding to I to join the Women's Medical Service receiv sufficient sum for a first-class passage to India. landing they are posted to one of the larger wom hospitals to gain Indian experience and to learn language. During this period (from six months to years) private practice is not allowed. For a fur period they are appointed to act temporarily medical women on furlough, during which t private practice is allowed. They are then defini appointed to the charge of hospitals. Private p tice is always allowed after the first two years, vided it does not interfere with official duties. only exception is in administrative or educati posts, when an allowance in lieu of practice is gi The amount obtained from practice varies accor to the station, but in most cases it forms a fair addi to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especi gynæcological—are found in the Women's Med Service. To those who are not keen surgeons op tunities are likely to open in the future in conne with maternity and child welfare; medical wo with administrative ability are also needed for inspection of women's hospitals and other me institutions.

Rates of pay are as follows :—

Years of service.	Overseas allowance per mensem.	Salary per mensem.	Englis equivale per ann
1 to 3	Rs.100	Rs.450	£440
4 to 6	,, ...	Rs.500	£480
7 to 9	,, ...	Rs.550	£520
10 to 12	,, ...	Rs.600	£560
13 to 15	Rs.150	Rs.650	£600
16 to 18	,, ...	Rs.700	£640
19 to 21	,, ...	Rs.750	£680
22 to 24	,, ...	Rs.800	£720
over 24	,, ...	Rs.850	£760

* At rupee value 1*s.* 4*d.*

Furnished quarters are provided, representing additional Rs.150 per mensem.

The cost of living in India is much higher t formerly, but it should be possible for a me woman (with house provided) to meet actual housel expenses for about Rs.200 per mensem, leaving remainder of her salary for dress and personal exper To this must be added the necessary saving to n additional expense for furlough and leave spen the hills.

One month's privilege leave on full pay is gra each year. Furlough on half-pay at the rate of months for every year of service is granted after ev three years. Study-leave on two-thirds pay is gra to the extent of 12 months in the total service. Th is a provident fund to which members of the ser contribute 10 per cent. of their pay. The ser contributes another 10 per cent., which accumulate interest and is repaid on retirement.

Admission to the service is made by selection. C didates in the United Kingdom should apply to Hon. Secretary, United Kingdom Branch of Countess of Dufferin's Fund, care of Major-Gen J. B. Smith, India Office, Whitehall, London.

DONATIONS AND BEQUESTS.—The late Mr. F. Ll of London and Sittingbourne, left, among other bequ £1000 each to the Croydon General Hospital, the Croy Social Service League (upon trust to provide holidays or otherwise for the benefit of, crippled children of Croyd Lord Mayor Treloar's Cripples' Hospital and College, A and Mrs. J. A. Spender, of Chantrey-place, Marden, Kent such public or charitable purposes as she, in her abs and uncontrolled discretion, may think fit).

SPECIAL DIPLOMAS.

DIPLOMA IN TROPICAL MEDICINE.

LTHOUGH a qualification in tropical medicine has been made registrable by statute, a diploma is rded as indispensable for appointments in the nial Medical Service and similar positions abroad. ematic instruction for these diplomas is given at ncorporated Liverpool School of Tropical Medicine nded in 1898) and at the London School of iene and Tropical Medicine, 23, Endsleigh-ens, Euston-road, N.W.

niversity of Cambridge.—The examination for the oma in Tropical Medicine and Hygiene is divided two parts. Part I. is held in Cambridge in l and Part II. in July in London. Candidates Part I. are examined under the same regulations in the same subjects as candidates for the Diploma 'ublic Health, but any qualification in medicine rgery recognised by the proper authority of any try outside the British Dominions may be gnised. The subjects for Part II. are Medicine, ery, and Hygiene in their relation to Tropical ase.

ie examination will be partly in writing, partly and partly practical or clinical (the clinical will be conducted at a hospital for tropical ses, at which cases will be submitted for diagnosis comment). Every candidate who passes the ination to the satisfaction of the examiners will ve from the University a diploma (D.T.M. & H.) fying to his knowledge and skill in tropical icine and hygiene.

rther information respecting the courses of study examinations may be obtained from Mr. J. E. is, Public Health Chemical Laboratory, Cam-ge.

niversity of London.—The M.D. degree may be n in tropical medicine at an examination held e annually, for which a thesis may be submitted.

niversity of Liverpool.—The University grants iploma in Tropical Medicine. At the end ach full course an examination is held by University for its Diploma of Tropical Medi- (D.T.M.), which is open only to those who been through the course of instruction of the ol. The subjects of examination are (*a*) Tropical ology, Parasitology; (*b*) Entomology; (*c*) ical Hygiene and Sanitation; (*d*) Tropical cine, including Ætiology, Symptoms, Diagnosis, Treatment of Tropical Diseases. The advanced se consists entirely of Practical and Clinical oratory Work, given at the laboratory at the ersity. Applications should be made to the n of the Medical Faculty, University of Liverpool.

diploma in Tropical Hygiene (D.T.H.) has tly been established. The subjects of examina- are bacteriology, chemistry (including meteor- y and climatology), entomology, protozoology, helminthology; tropical sanitation (including ary engineering); practical sanitation. Two ersity Fellowships of £100 a year each are open udents of the school, amongst others. Accom- ation for research work is to be had at the ersity Laboratory. The Mary Kingsley Medal warded by the school for distinguished work nnexion with Tropical Medicine.

njoint Board R.C.P. Lond., R.C.S. Eng.—The oma of D.T.M. & H. Eng. is awarded on the ts of an examination held twice yearly, in uary and July. Candidates must possess a trable qualification, and produce evidence of ng attended (1) practical instruction in pathology, ozoology, helminthology, entomology, bacterio- and hygiene in relation to tropical medicine in cognised institution during not less than five ths; (2) clinical practice of a recognised hospital he same period. Conditions of study may be ified in the case of candidates of special experience. Notice of entry to the Secretary, Examination Hall, Queen-square, London, W.C.

University of Edinburgh.—Candidates for the Diploma in Tropical Medicine and Hygiene must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body. The course of instruction is given during the autumn term, October to December, and includes Tropical Hygiene, Bacteriology, Entomology and Parasitology, and Diseases of Tropical Climates (systematic and clinical). Provision is made in the University for instruction in all subjects. The examinations are written, oral, and practical, and are held twice yearly—viz., June and December. Candidates are required on the first occasion of presenting themselves for examination to appear for all the subjects. Candidates who fail to pass the entire examination within a period of 12 months after first appearance are required to reappear for all the subjects. The University is included in the list of Institutions whose courses of instruction in Tropical Medicine may be taken by officers of all Colonial Medical Services on first appointment or during study-leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

DIPLOMA IN BACTERIOLOGY.

The University of London has instituted an academic diploma in bacteriology, and a full time course covering this diploma will be opened on Oct. 4th by the London School of Hygiene and Tropical Medicine. This course will be held at 6, Gordon-square, London, W.C. 1, pending the opening of the new buildings behind the British Museum which are now under construction. The diploma is open to graduates in medicine, science, or pharmacy of London or of any other approved university. Registered medical practitioners or other non-graduate students who have obtained a qualification and undergone a previous training which in the opinion of the University has fitted them to profit by the instruction may be admitted. The course of study, which extends over an academic year, is divided into two parts, of which the first is concerned with bacteriological principles and with general technique. The second part of the course is to be devoted to bacteriology applied to (1) clinical medicine, (2) hygiene, or (3) industry, at the selection of the candidate.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Universities of Cambridge, London, Durham, Leeds, Manchester, Edinburgh, Dublin, National University of Ireland, and the Conjoint Board of the R.C.P. Lond. and R.C.S.Eng. now grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses; the details on these points can be obtained from the various examination bodies.

In London, courses of instruction for the Diploma in Psychological Medicine are given at the Maudsley Hospital, Denmark Hill, which has recently been definitely recognised as a school of the University of London. The course consists of two parts, and is adapted for the diploma of the Conjoint Board, the University of London, or the University of Cambridge.

Maudsley Hospital.—Appointments as clinical assistants are obtainable at the Maudsley Hospital. The holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. The appointments and other facilities for clinical experience are open to qualified medical practitioners apart from the courses of instruction. Inquiries as to lectures should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital,

Denmark Hill, S.E.; and as to clinical facilities, to the Medical Superintendent at the same address.

Bethlem Royal Hospital.—A course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by the various universities and the Conjoint Board, is held at Bethlem Royal Hospital, Lindon, S.E., twice annually, during the spring and autumn. The fee for the full course is 15 guineas. Part A or Part B, however, may be taken separately at a fee of 10 guineas per part. In addition to the above, clinical instruction in Psychological Medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 A.M. The fee for students is 3 guineas for a period of three months' attendance and for post-graduates a fee of 5 guineas for a like period. A reduction is made to those who attend the Diploma Course. House physicians are appointed at Bethlem Royal Hospital for a term of six months, which may be extended. These appointments are made on May 1st and Nov. 1st in each year and the vacancies are advertised in the medical papers. Apartments, complete board, attendance, and laundry are provided and also a salary at the rate of £100 per annum. Clinical assistants are often appointed from time to time for periods of three months or longer. These are non-salaried and non-resident posts, but partial board is provided. The Physician-Superintendent, Bethlem Royal Hospital, will supply further particulars.

University of Edinburgh.—Candidates for the Diploma in Psychiatry must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body. Candidates are required subsequent to the date of graduation or obtaining a registrable qualification to have held (*a*) a resident appointment for one year in a hospital for mental disorders approved by the Faculty of Medicine, or alternatively (*b*) a six months' appointment as defined in (*a*) and six months' practical study of nervous diseases in a special or general hospital approved by the Faculty of Medicine. There are two examinations for the Diploma. Part I. comprises 1. Anatomy of the Nervous System. 2. Physiology of the Nervous System. 3. Psychology and Experimental Psychology. Part II. comprises: 1. Neuropathology. 2. Clinical Psychiatry. 3. Clinical Neurology. 4. An additional subject selected by the candidate from a prescribed list. The examinations are held twice yearly in March and July. Candidates who have held an asylum appointment for a period of five years or more may be exempted from the course of study in one or more subjects of the curriculum. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Dublin University.—A post-graduate diploma in Psychological Medicine is conferred upon registered medical practitioners who have held a resident medical appointment at a recognised institution for the treatment of Mental Diseases for 12 months, or who have held such an appointment for six months and have attended clinical instruction at an approved institution for six months. Candidates must also attend special courses of instruction and pass a special examination. Details can be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

The National University of Ireland and the *Conjoint Board of the Royal Colleges of Ireland* confer a diploma in Psychological Medicine upon similar terms; application should be made to the Registrar of the School of Physic and the Secretary of the Board respectively.

DIPLOMA IN OPHTHALMIC MEDICINE.

Special diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford.—The diploma in ophthalmology (D.O.) is granted to registered medical practitioners after passing an examination, held annually in March, which is open to candidates who have pursued at Oxford a course of study in ophthalmology ove period of at least two months and who have atten a 12 months' recognised hospital course. Furt information regarding these requirements may obtained from the Dean of the School of Medicin

Conjoint Board R.C.P. Lond., R.C.S. Eng.—' Conjoint Board grants the D.O.M.S. after an e mination held in two parts, twice yearly January and July. Part I. comprises anato and embryology of the visual apparatus, physiol of vision, and elementary optics. Part II. compr optical defects, ophthalmic medicine and surg and pathology with special reference to ophthalmol The examination in each case is written, oral, practical or clinical. Candidates may only enter Part II. on completion of a year of special study of o thalmology after obtaining a registrable qualificati

DIPLOMA IN MEDICAL RADIOLOGY AN ELECTROLOGY.

University of Cambridge.—This Diploma is o only to those who hold a medical qualification. includes a course of lectures and practical work Physics (Part I.) and in Radiology and Electrol (Part II.). Attendances at the necessary courses lectures in both subjects, and, in addition, six mon clinical experience in an adequately equipped hosp recognised by the Committee, are essential. whole course of study takes six months, though is likely to be increased in the future, the lectu practical work, and hospital attendance runn concurrently. Two courses of study are now re nised by the University of Cambridge. One co begins in London in October in preparation for examination in Part I. in January and in Part in the following April. The other course begins Cambridge in January in preparation for the exami tion in Part I. in April and in Part II. in July. the Cambridge course three months are spent Cambridge doing the lectures and practical work Part I., attending the lectures in Part II., and atte ing the practice of Addenbrooke's Hospital. remaining three months can be completed at recognised hospital, but special arrangements made for candidates to continue their studies London.

A six months' course is arranged by the Bri Institute of Radiology held entirely in London, is recognised by the University as qualifying for examination, and begins early in October. Fur particulars as to the Cambridge Course can be obtai from Mr. G. Stead, M.A., Cavendish Laborato Cambridge, and of the London Courses from Stanley Melville, at the offices of the B.I 32, Welbeck-street, London, W.

University of Edinburgh.—Candidates for Diploma in Radiology (D.R. Univ. Edin.) must graduates in medicine and surgery of the Univer of Edinburgh or hold corresponding registr degrees or qualification from some other licen body. Candidates are not admitted to the examina for the Diploma until after the lapse of not less t one year from obtaining a registrable qualificat which qualification must be registered before admis to the Examination. The course of study begin October and extends over a period of not less t three terms. The Examination, which is writ oral, and practical, is in two parts: (*a*) Physics, (*b*) Radiology. The Examination is held twice ye —viz., July and October. Full particulars ma obtained from the Dean of the Faculty of Medic

DIPLOMA IN LARYNGOLOGY AND OTOLO

The Conjoint Board R.C.P. Lond., R.C.S. E grants the D.L.O. after an examination held two parts, twice yearly, in June and Decem Part I. comprises anatomy, embryology, and phy logy of the ear, nose, pharynx, larynx, trachea bronchi, and œsophagus. Part II. comprises

cine, surgery, and pathology of the ear, nose, ynx, larynx, trachea and bronchi, and œsophagus, the recognition and use of special instruments appliances. The examination in each case is en, oral, and practical or clinical. Candidates only enter for Part II. on completion of one year ecial study of the diseases of the ear, nose, ynx, and larynx, after obtaining a registrable fication. The fee for admission to each part is neas.

IPLOMA IN TUBERCULOUS DISEASES.

Diploma in Tuberculous Diseases is given by the ersity of Wales. Candidates must possess a cal qualification registrable for practice in Great in and Ireland, and be not less than 25 years of and either (Category A) have held, for a period t less than five years, whole-time appointments ork in tuberculosis; or (Category B) have held istrable qualification to practise for at least one and presented (*a*) a certificate of satisfactory ance of a course of consecutive post-graduate of the clinical and epidemiological aspects of culosis of six months' duration at a recognised ersity, medical school, or hospital where such rse is given; or, alternatively, a certificate of ear's post-graduate work as a whole-time member e staff of a tuberculosis hospital, sanatorium, or nsary approved by the Ministry of Health, signed e representative of the authorities for whom the was performed or by the administrative medical r concerned; (*b*) a certificate of satisfactory ance of a course of consecutive post-graduate ical study of the Pathology and Bacteriology of rculosis of three months' duration at a tubercu- laboratory or a recognised general laboratory e such a course is given; (*c*) a certificate of three hs' satisfactory attendance at a tuberculosis ute or dispensary.

e examination is divided into two parts and the ; £10 10*s*. Applications should be made to the strar of the University, University Registry, ays Park, Cardiff, not later than May 15th.

e Cecil Prosser Research Scholarship, of the value 50 for one year, is awarded triennially for research berculosis.

DIPLOMA IN PUBLIC HEALTH.

E following epitomises the instruction given at us universities and centres of medical education edical men desiring to obtain diplomas in sanitary ce, public health, hygiene or State medicine, is discipline is variously called. Resolutions, ned with a view of ensuring "the possession of a actively high proficiency, scientific and practical, the branches of study which concern the public h," have been adopted at various times by the ral Medical Council. The diploma is registrable he Council, whose rules on the curriculum become ing on the educational bodies concerned. The regulations, which came into force in 1923, d the period of study and postpone the granting diploma until at least two years from qualification.

Joint Board of the R.C.P. Lond. and R.C.S. Eng.—The regulations came into force on Jan. 1st, , which apply to all candidates who have not nenced bonâ-fide study of Public Health in dance with the above regulations before that They are as follows: The Examination sts of two Parts. Part I. will be held in the hs of January and June, and Part II. in months of January and July in each year. lidates may enter for Parts I. and II. separately the same time, but they must pass Part I. before eeding to Part II. The Examination in each will be written, oral, and practical. Part II. include a practical examination in Infectious ases, Food Inspection, and Inspection of selected nises. Candidates who fail to satisfy the Examiners in either part may present themselves again at the next Examination on payment of the same Fees. Candidates intending to present themselves for either part of the Examination must give 14 days' notice in writing to the Secretary, at the Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

Candidates will be admissible to Examination in Part I. on producing evidence:—

1. Of being in possession of a registrable qualification in Medicine, Surgery, and Midwifery.
2. Of having attended during a period of not less than five months at an Institution recognised by the Examining Board in England, practical instruction in (*a*) Bacteriology and Parasitology (including Medical Entomology) especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical laboratory work. (*b*) Chemistry and Physics in relation to public health, during 90 hours, of which not less than 70 hours have been occupied in practical laboratory work. (*c*) Meteorology and Climatology in relation to public health, during not less than 10 hours.

Candidates will be admitted to Part II. of the Examination on producing evidence:—

1. Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery during not less than two years, of being registered by the General Medical Council, and of having completed the curriculum for the Diploma extending over a period of 12 calendar months subsequent to the attainment of a registrable qualification.
2. Of having attended, after obtaining the registrable Qualification, instruction during not less than 80 hours at an Institution recognised by the Examining Board in England in the following subjects:—(*a*) The Principles of Public Health and Sanitation for not less than 30 hours; (*b*) Epidemiology and Vital Statistics for not less than 20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours; (*d*) Sanitary Construction and Planning during not less than 10 hours.
3. Of having attended for three months the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England and of having therein received instruction in the methods of administration. The Certificate must state that the candidate has attended on one or more days in each week of the three months, that each attendance was of two hours' duration, with a total attendance of 60 hours.
4. Of having been engaged during a period of not less than six months in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a Medical Officer of Health, and of having received, from such officer or other competent Medical Officer during not less than three hours on each of 60 working days, practical instruction in those duties and also those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for children of school age, (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food; including meat and milk.

The above certificate (4) must be obtained from a Medical Officer of Health who devotes his whole time to public work, or from a Medical Officer of Health of a Sanitary Area having a population of not less than 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

University of Oxford.—An examination, conducted partly in writing, partly vivâ voce, and in each subject partly practical, is held in Michaelmas and in Trinity Term in the following subjects:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II.

The First Part of the examination will comprise (*a*) written papers of three hours each in (i.) Chemistry and Physics, and (ii.) Pathology and Bacteriology; (*b*) a three hours' practical and vivâ voce examination in Chemistry and Physics; (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

The Second Part of the Examination will consist of the following parts:—(*a*) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and

the Laws relating to Public Health); (*b*) a practical and vivâ voce examination in General Hygiene; and (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce certificates (1) of Laboratory Work in Chemistry, Physics, Meteorology, and Climatology as applied to Hygiene, and (2) of having had Practical Instruction in Bacteriology and Parasitology and the Pathology of the Diseases of Animals transmissible to Man.

Candidates in Part II. will produce the following further certificates: (3) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration.

All the above degrees are now open to Women Students, and particulars of Scholarships and Prizes may be obtained from the Principals of the various Ladies' Colleges. The names of candidates for the Diploma in Public Health must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford. Applications for any further information should be addressed to the Dean, Department of Medicine, Museum, Oxford.

University of Cambridge.—Two examinations in so much of State medicine as is comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) Part I. of the examination; or (2) Part II. of the examination. Candidates must before admission to either part of the examination produce evidence of having satisfied the regulations applicable to Part I. and Part II. The examination for Part I. is in April and for Part II. in October.

For Part I. of the examination courses of lectures and laboratory instruction are given in the University on Hygiene, Chemistry, &c., and on Bacteriology and Parasitology. For Part II. the Medical Officer of Health for Cambridge gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital; and the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology. There are also courses by special lecturers in Vital Statistics, Tuberculosis Service, Venereal Diseases Service, Industrial Hygiene, Maternity and Child Welfare. These courses are open to non-members of the University.

A special Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England. The courses and examinations are the same as for the Diploma in Public Health (except that the candidates are not examined in English Sanitary Laws).

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Public Health Chemical Laboratory, Cambridge.

University of London.—Candidates for the M.D. Degree may offer State Medicine as a subject in which to graduate. The regulations have been revised and may be obtained on application to the Academic Registrar, University of London, South Kensington.

University of Durham.—The Degree of Bachelor of Hygiene (B.Hy.) and the Diploma in Public Health (D.P.H.).—No candidate is admitted to the final examination for the Degree of B.Hy. unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognised University, and no candidate is admitted to the final examina for the D.P.H. unless he is a registered med practitioner, of not less than two years' standing. course of study for the B.Hy. and D.P.H. ext over a period of not less than 12 calendar mon subsequent to the attainment of a registrable qu cation. Candidates for the B.Hy. must attend course at the University of Durham; candid for the D.P.H. may attend it at the Universit Durham, or at any medical school or institution w is recognised by the University. The examina for the diploma or degree is divided into two p A candidate must pass in all the subjects of Pa before being admitted to examination for Part In Part I., and also in Part II., a candidate must in all the specified subjects at one time. The exam tion for Part I. is practical, written, and and includes the following subjects: Bacterio and Parasitology (including medical entomolo Chemistry and Physics, and Meteorology and Cl tology, in relation to Public Health. Candidates not admitted to examination for Part I. until they have completed the prescribed courses of ins tion in the subjects thereof. The examinatio Part II. includes Hygiene and Sanitation (compr sanitary construction), Epidemiology and Infec Diseases; Sanitary Law and Vital Statistics; P Health Administration. The examination is wr and oral, and includes practical examination Infectious Diseases, Food Inspection, Inspectio Premises—Dwellings, Factories, Workshops, Sch &c. Candidates are not admitted to examin for Part II. until after they have completed prescribed courses of instruction in the sub thereof. Doctor of Hygiene (D.Hy.): Candi must be Bachelors of Hygiene of two years' stan and are required to satisfy the examiners that have conducted original research in the subje Public Health.

Victoria University of Manchester.—An examin in Public Health is held twice yearly. The examin is in two parts and is written, oral, and prac Candidates may present themselves for Parts I. II. separately or at the same time provided tha candidate be admitted to Part II. unless he has alr passed in Part I. No candidate's name will be lished until he has satisfied the examiners in both of the examination. Every candidate who passed both parts of the examination to satisfaction of the examiners, and who is le registered, will receive a Diploma in Public H The examination will begin about the middle of and the middle of October in each year. Holde the Diploma in Public Health are eligible for exa tion for the Certificates in School Hygiene and Fa Hygiene after attending the prescribed perio study and hospital practice. An examination Diploma in Bacteriology is held for graduat science or medicine who have attended presc courses for at least one academic year; candi must present a satisfactory thesis on an app subject.

University of Birmingham.—Under the re rules and regulations of the General Medical C the University grants a degree of B.Sc. in P Health and also a Diploma in the same su on the following conditions: Graduates in Me of this University may become candidates fo degree of Bachelor of Science in Public H by conforming to all the requirements laid for candidates for the Diploma in Public H except that after graduating in Medicine all c of study must be taken out in the Unive and they must, in addition, have attended a months' course of Geology in the University. A on the Ætiology and Prevention of a Disease of the candidate has made a special study mu submitted on entry for B.Sc. Part II. The examin will be held in the months of March and Oc and will consist of two parts, each part being wi oral, and practical. No candidate will be allow

Part II. until he has passed Part I. Candidates enter for Parts I. and II. separately or at the time. The fee for each part of the examination 5s. Medical Officers of the Royal Navy who have ıded the required course of study at the Naval cal School, Greenwich, will be admitted to Part I. ıinations for the Diploma in Public Health, her they have previously been students at the ingham School or not; and the same applies to rs of the Royal Army Medical Corps who have ed at the Staff College. Medical Officers of the y and Army are admitted to Part II. Examination .H.) on complying with the requirements laid ı for attendance upon Courses of Study. These ses need not necessarily be attended in the ersity of Birmingham.

iversity of Liverpool.—The University grants a ee in Hygiene (M.H.) and a Diploma (D.P.H.), every facility is afforded for training in Sanitary ce and State Medicine. The curriculum for the ee extends over a period of two years, the first hich is devoted to laboratory instruction and ical classes (including those for the Diploma); second being devoted to advanced study and rch. The courses may be taken at any time, students are allowed to work daily in the atories.

iversity of Leeds.—The University grants a oma in Public Health, and every facility is ded for training in Sanitary Science and State cine. The examination, which is held twice in year—namely, in June and December—is in parts, and is written, oral, and practical. Can- es must pass in Part I. before being admitted to II. Instruction in Entomology and Meteorology en in the first term, and in Sanitary Chemistry Bacteriology in the second and third terms. ical work under arrangement with the Leeds Council. Prospectus can be obtained from the emic Sub-Dean of the Medical School.

iversity of Bristol.—Diploma in Public Health. idates must be at least 23 years of age, shall be registered medical practitioners of not less than years' standing as such, and shall have passed examination prescribed by regulation. The ination is divided into two parts.

iversity of Wales.—Candidates for the Diploma ıblic Health, the curriculum for which extends a period of not less than twelve calendar months quent to the attainment of a registrable qualifi- n, must produce evidence of having attended ot less than five months at the Welsh National ol of Medicine or at an institution approved by ourt, practical instruction in Bacteriology and sitology, Chemistry and Physics, and Meteorology limatology in relation to Public Health. Candi- must satisfy the examiners that they have ved instruction approved by the University in Principles of Public Health and Sanitation, emiology and Vital Statistics, Sanitary Law Administration, and Sanitary Construction and ning. The candidate must also produce evidence he has attended for three months on the clinical ice of a hospital for infectious diseases con- ng not less than 100 beds, and has received therein uction in the methods of administration, and that us for a period of not less than six months been ged in acquiring a practical knowledge of the s, routine and special, of a public health nistration under the supervision of a medical r of health. The examination for the diploma ided into two parts, Part I. and Part II., each of n extends over not less than two days. A candi- must pass in all the subjects of Part I. before admitted to Part II. of the examination. In I., and also in Part II., a candidate must pass the specified subjects at one time. Part I. of the ination is practical, written and oral, and comprises eriology and Parasitology (including Medical mology); Chemistry and Physics, and Meteoro- and Climatology in relation to Public Health. Candidates may not be admitted to Part I. of the examination until they have been certified as having pursued the prescribed courses of instruction in the subjects thereof. Part II. of the examination, which is written and oral, comprises: Hygiene and Sanitation (including Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. No candidate can be admitted to Part II. of the examination until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, Surgery, and Midwifery, which qualification must be registered before admission to Part II. of the examination. An examination in each part will be held annually. The examination in Part I. will be held in June, that in Part II. in October. Full information from the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 15th for the examination in Part I. and not later than Sept. 1st for the examination in Part II.

University of Edinburgh.—Candidates for the Diploma in Public Health must be graduates in medicine and surgery of the University, or hold corresponding degrees or registrable medical qualifications which must be registered before admission to examination. The course is divided into two parts for which examinations are held twice yearly, in March and July for Part I., and in October and December for Part II. In each part the candidate must pass in all the specified subjects at one examination. Candidates are not admitted to Part II. until they have passed Part I., nor until after the lapse of not less than two years from the date of obtaining a registrable medical qualification. The subjects of the examination are: Part I. (written, oral, and practical), Bacteriology; Medical Entomology and Parasitology; Chemistry, Physics, Meteorology, and Climatology. Part II. (written, oral, and practical), Hygiene, Sanitation, and Sanitary Construction; Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. There is also included practical examinations in Infectious Diseases, Food Inspection, and Inspection of Premises. The course, which extends over a period of 12 calendar months, begins in October, and provision is made by the University for instruction in all the subjects. Detailed particulars may be obtained from the Dean of the Faculty of Medicine.

University of Aberdeen.—Every candidate for the Diploma in Public Health must be a graduate in medicine of the University of Aberdeen, or of any other University whose medical degrees are recognised as qualifying for registration by the General Medical Council of the United Kingdom. No candidate will be admitted to the Final Part of the Examination for the Diploma until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, which qualification shall have been registered before such admission. The whole of the prescribed curriculum of study must be undertaken after the candidate has obtained a registrable qualification in medicine, and shall extend over not less than twelve calendar months. At least one academic term must be spent at the University of Aberdeen. Every candidate shall produce evidence of having complied with the following requirements in respect of study and training:—1. Practical instruction in the following subjects within a laboratory or laboratories approved by the University: (*a*) Bacteriology and Parasitology (including Medical Entomology), in relation to diseases of man and diseases of lower animals transmissible to man—at least 180 hours, of which not less than 150 shall be occupied in practical laboratory work; (*b*) Chemistry and Physics, in relation to Public Health—at least 90 hours, of which not less than 70 shall be occupied in practical laboratory work; (*c*) Meteorology and Climatology, in relation to Public Health—at least 10 hours; such instruction to extend over not less than five months or two academic terms. 2. A course or courses of

instruction extending over not less than 80 hours dealing with: (*a*) The Principles of Public Health and Sanitation—30 hours; (*b*) Epidemiology and Vital Statistics—20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services)—20 hours; (*d*) Sanitary Construction and Planning—10 hours; such course or courses to be given at an institution or by a teacher or teachers approved by the University. 3. Practical instruction, clinical and administrative, within a recognised hospital for general infectious diseases; such instruction to extend over three months, and to include 30 daily attendances of not less than two hours in each week. 4. Practical instruction and experience, during not less than six months (including attendance of at least three hours on each of sixty working days) in the duties, routine and special, of public health administration, under the supervision of a medical officer of health, who shall certify that the candidate has received from this officer or other competent medical officer, practical instruction in these duties, and also in those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. The medical officers of health recognised for this purpose by the General Medical Council are: (*a*) a medical officer of health who devotes his whole time to public health work; or (*b*) the medical officer of health of a sanitary area having a population of not less than 50,000; or (*c*) in Ireland, the medical superintendent officer of health of a county or county borough having a population of not less than 50,000. The examination for the diploma is divided into two parts, each of which extends over not less than three days.

University of Glasgow.—Degree of B.Sc. in Public Health.—Candidates must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose by the University Court. Candidates must produce evidence (1) that, after they have obtained a registrable Degree in Medicine, a period of not less than two years has elapsed; (2) that, after they have obtained a registrable degree in Medicine, they have, during a period of not less than 21 calendar months, pursued the course of work and instruction prescribed, and have satisfied the examiners in the prescribed examinations. There are two examinations. Part I. includes the following subjects: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health; (iv) Higher Chemistry in relation to Public Health; (v) Physics and Geology. A candidate must pass in the subjects marked (i), (ii), and (iii) of Part I. at one examination. Part II. includes the following subjects: (vi) Hygiene and Sanitation (including Sanitary construction); (vii) Epidemiology and Infectious Diseases; (viii) Sanitary Law and Vital Statistics; (ix) Public Health Administration; (x) Applied Hygiene. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like. The examination in Applied Hygiene may be on a selected subject professed by the candidate. A candidate must pass in the subjects marked (vi), (vii), (viii), and (ix) of Part II. at one examination. *Diploma in Public Health (D.P.H.).*—Candidates for this Diploma must be legally qualified medical practitioners who are matriculated students of the University. A period of not less than two years must elapse between the attainment by the candidate of a registrable medical qualification, and his admission to the final examination (Part II.) for the Diploma. The candidate must, during a period of not less than 12 calendar months, subsequent to his attainment of a registrable medical qualification, pursue the course of work and instruction prescribed, and pass the prescribed examinations. The examination, which is both written oral, is divided into two parts, Part I. and Part each of which extends over not less than two d No candidate is admitted to either part of the ex nation until he has completed the prescribed co of instruction in the subjects of that part. candidate is admitted to Part II. until he has pa in all the subjects of Part I., nor until after the l of not less than two years from the date of his ob ing a registrable medical qualification, nor u he presents a certificate showing that his name qualification have been duly registered in the Me Register. Part I. includes: (i) Bacteriology Parasitology (including Medical Entomology); Chemistry and Physics in relation to Public Hea (iii) Meteorology and Climatology in relatio Public Health. A candidate must pass in all subjects at one examination. Part II. inclu (iv) Hygiene and Sanitation (including Sani Construction); (v) Epidemiology and Infect Diseases; (vi) Sanitary Law and Vital Statis (vii) Public Health Administration. A candi must pass in all the subjects at one examina The examination for Part II. includes prac examinations in Infectious Diseases; Food In tion; Inspection of Premises, such as dwell factories, workshops, schools, and the like.

University of St. Andrews.—The Diploma Public Health is open to those who hold a regist medical qualification of the United Kingdom. examination is in two parts. (1) (*a*) Bacteriology Parasitology; (*b*) Chemistry and Physics; (*c*) Mete logy and Climatology. (2) Public Health and Sanita Epidemiology and Vital Statistics, Sanitary Law Administration, and Sanitary Construction Planning. Before admission to the first examina the candidate must have held his medical qualifica for one year, and before admission to the se examination for two years. Graduates in Med of the University of St. Andrews may take pa all of the qualifying classes in any University o United Kingdom, or in any Indian, Colonial, or For University or medical school recognised by University Court, but holders of other regist medical qualifications must spend at least eight of the 12 months' curriculum in St. Andrews Un sity. A complete course is given in the Con Medical School, Dundee. The examination fe each division is £5 5*s*.

University of Dublin (Trinity College).—The Dipl in Public Health is conferred, after examination, u the following conditions. The candidate must registered medical practitioner and have obtain registrable qualification at least two years b the second part of the examination. The candi must have completed, subsequently to obtainin registrable qualification, five months' prac instruction in a chemical and bacteriological lab tory, or laboratories, approved by the Univer must have received instruction in the follo subjects: the principles of public health and tation, epidemiology and vital statistics, san law and administration (including public me services), sanitary construction and planning; have studied, practically, outdoor sanitary work six months under an approved officer of health, must have attended for three months at a hospital where opportunities are afforded for study of methods of administration. A sp prospectus may be obtained by application to Registrar of the School of Physic, Trinity Col Dublin.

*National University of Ireland.**—At this Unive there is a Dipioma in Public Health, a B.Sc. in P Health, and a D.Sc. in Public Health.

University of Belfast.—A Diploma in Public H is given by examination. Every candidate produce evidence that, after obtaining a regist qualification, he has during six months rec

* No returns.

tical instruction in an approved laboratory in h Chemistry, Bacteriology, and the Pathology he diseases of animals transmissible to man are ht. After obtaining a registrable qualification y candidate must produce evidence that he has nded during three months the practice of a ital for infectious diseases at which opportunities afforded for the study of methods of administra-. The examination must have extended over not than four days, one of which shall have been oted to practical work in a laboratory, and one ractical examination in, and reporting on, subjects h fall within the special outdoor duties of a ical officer of health. The first part of the examin- will have reference to the general principles of tary Science and the second part to State Medicine to the applications of Pathology and Sanitary nce. The examination in both parts is held e a year, in March and June.

oyal College of Physicians of Edinburgh, Royal ge of Surgeons of Edinburgh, Royal Faculty of sicians and Surgeons of Glasgow.—All candidates the Diploma in Public Health must have a ification which has been registered under the ical Acts. Candidates must have attended not than four calendar months' practical instruction hemistry and Physics (90 hours), Bacteriology Parasitology (180 hours), and Meteorology and atology (60 hours) in a recognised laboratory or ratories, must have studied outdoor sanitary work six months under a medical officer of health or r sanitary officer; and must give evidence of ndance for three months at the practice of a ital for Infectious Diseases, at which he has ved instruction in the methods of administration. examination consists of two parts, and candidates enter for both at one period or for either separately. First Part includes (*a*) Laboratory Work (Chem- and Bacteriology), (*b*) Physics and Meteorology; the Second Examination embraces (*a*) Report remises visited, (*b*) Examination at Fever Hospital, xamination at Public Abattoir, (*d*) Written and Examinations on Epidemiology and Endemiology, ital Statistics and Sanitary Law, and (*f*) Practical tation. The fee is 12 guineas for both examina-, or 6 guineas for either of them. A fee of ineas is payable by rejected candidates for either ination. The examination is held twice yearly, ay in Glasgow, and October in Edinburgh. The lished regulations provide detailed synopses of the ects of examination. *The curriculum and examina- have been adjusted fully to meet the requirements of egulations of the General Medical Council which into force on Jan. 1st, 1924.* Candidates applying Regulations should state date of commencement rriculum. The Registrar for Edinburgh is Mr. . Eadie, 49, Lauriston-place, and for Glasgow Walter Hurst, 242, St. Vincent-street.

oyal College of Physicians of Ireland and Royal ge of Surgeons in Ireland.—Every candidate the Diploma in Public Health must observe following rules: 1. A period of not less than years shall elapse between the attainment a candidate of a registrable qualification in cine, Surgery, and Midwifery, and his ad- ion to the Final Examination for a Diploma ublic Health. 2. The curriculum for a Diploma Public Health shall extend over a period of less than 12 calendar months subsequent to attainment of a registrable qualification. Every candidate shall produce evidence of ng attended, during a period of not less than months, at an institution approved by the sing Body granting the Diploma, practical uction in—(*a*) Bacteriology and Parasitology uding Medical Entomology), especially in their ion to diseases of man, and to those diseases of ower animals which are transmissible to man; Chemistry and Physics in relation to Public th; (*c*) Meteorology and Climatology in relation ublic Health. At least 180 hours must be devoted to Course (*a*), of which not less than 150 hours shall be occupied in practical Laboratory work. At least 90 hours must be devoted to Course (*b*), of which not less than 70 hours shall be occupied in practical Laboratory work. At least 10 hours must be devoted to Course (*c*). 4. Evidence of having received, during not less than 80 hours, at an institution or from teachers approved by the Licensing Body granting the Diploma, instruction in the following subjects: (*a*) The Principles of Public Health and Sanitation; (*b*) Epidemiology and Vital Statistics; (*c*) Sanitary Law and Administration (including Public Medical Services); (*d*) Sanitary Construction and Planning. 5. Evidence that he has attended for three months on the clinical practice of a recognised Hospital for Infectious Diseases. 6. Evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a Medical Officer of Health. The examination for the Diploma is divided into two parts. The examination for Part I. includes Bacteriology and Parasitology (with Medical Entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. The examination for Part II. includes Hygiene and Sanitation (with Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination, which is written and oral, includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises—dwellings, factories, workshops and schools.

DENTAL SURGERY.

REGISTRATION on the Medical Register entitles a practitioner to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but few dental appointments at general or special hospitals or dispensaries are available save to those with a special diploma.

The Examining Bodies in Dentistry which grant degrees and honour diplomas in the subject are as follows: Royal College of Surgeons of England, Royal College of Surgeons, Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow, Royal College of Surgeons in Ireland, and the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Manchester, Sheffield, St. Andrews, Dublin (Trinity College), and Queen's University of Belfast. The respective requirements of the various examining bodies in dentistry are very similar, being designed to meet the requirements of the Dental Board, but the examinations vary in stringency, and each school has its rules for matriculation and exemption, and its scale of fees. The student should apply to the secretaries of the various Conjoint Boards or to the Deans of the medical faculties or medical schools for a syllabus.

TEACHING INSTITUTIONS IN DENTISTRY: LONDON.

Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.—A school of the University of London. Women are now admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for four months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the

Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £25. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25, open to pupils of the Hospital only. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses at the end of the summer and winter sessions. For full information as to scholarships and prizes, and other matters connected with the course, application should be made to the Dean.

University College Hospital Dental School, corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the *National Dental Hospital*, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. A prospectus containing full information as to lectures, fees, and prizes may be had on application to the Sub-Dean for Dental Students, who attends at University College Hospital Medical School, University street, W.C.1, on Wednesday mornings from 9.30 to 10.30, and at other times by appointment.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for both general and local anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrators, the dental house surgeons, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. There is a separate room for denture patients affording accommodation for 15 chairs and a separate department for children with accommodation for 20 chairs. The Members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by two demonstrators, a house surgeon, and five mechanics.

Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge.

Eighteen house surgeons, 15 assistant house surgeons, and four student demonstrators of Dental Histology are appointed annually. The follow appointments are held by students: Full surge dresser, assistant surgeon's dresser, dresser in children's department, casualty dresser, clerk to anæsthetist, dresser in the gas extraction and l anæsthetic extraction rooms, and probationary dres For particulars as to scholarships and prizes, as as all information, application should be made the Dean of the Medical School.

King's College Hospital.—The Dental School is of the Medical School of King's College Hospi and was opened in November, 1923. The De Out-patient Department of the Hospital is used the performance of dental extractions. A la Conservation Room with provision for 40 dental ch has been equipped. Smaller rooms are used for clin teaching and administrative requirements, an specially equipped laboratory for training in art of dental mechanics. An X ray apparatus been installed for special use in dental skiagra A museum containing a large number of specim illustrating oral, buccal, dental, and other dise is available for teaching purposes. The libr lecture theatre, lecture rooms, common rooms, the refreshment room are all available for the us students. Courses of study, including practical w are provided for the degree of Bachelor of De Surgery of the University of London, and for Diploma in Dental Surgery of the Royal Colleg Surgeons of England. Special arrangements are m for those students who wish to take a medical de or qualification in addition to a degree or diplom Dental Surgery.

The following salaried appointments are oper qualified members of the School: Registrar, Resi House Surgeon, Non-Resident House Surgeon, Tutor in Dental Mechanics.

Full particulars of the Dental School may obtained on application to the Dean, or to Secretary, King's College Hospital, Denmark London, S.E.

London Hospital.—This school is a part of London Hospital and Medical College, and is f equipped on the most modern lines and with latest appliances. It provides a complete curricu in all subjects for the B.D.S. Degree and for the L. Diploma, and is admirably adapted for the pur of teaching. The Conservation Room is well lig and ventilated and fitted with pump chairs of latest pattern; the fountain spittoons at man the chairs have been specially designed. spittoon has attached to it a saliva ejector, hot cold water, compressed air, gas and electric cur also a swing bracket to carry the students' cab Electric sterilisers are supplied in each departm and motor engines where required. The Sc possesses, in addition to the Theatres, Laborato and Museums in the College, a special Museur Dental Anatomy and Surgery, Operative Denti Prosthetic and Extraction Rooms, and Laborat for Practical Metallurgy and Prosthesis. A systen course of instruction is arranged for pupils. The up date Laboratory contains every modern appar and is in charge of a skilled curator and his assist Connected with the Medical College and Dental Sc are a Library, Athenæum, Clubs' Union, Dining with moderate tariff, Students' Hostel, and an Ath Ground. For full particulars as to Scholarships Prizes, fees and course of study advised, apply to Dean of the Medical School.

London (Royal Free Hospital) School of Med for Women.—Full courses are arranged for wo students in conjunction with the Royal De Hospital, Leicester-square, for the study of dentis and in preparation for the B.D.S. Degree of University of London and the Licence in De Surgery of the Royal College of Surgeons of Engl at the London (Royal Free Hospital) Schoo Medicine for Women.

PROVINCIAL TEACHING INSTITUTIONS.

irmingham Dental Hospital, Great Charles-street.—
n: Cyril Howkins, C.B.E., D.S.O., M.R.C.S.,
.S. The Dental Hospital has accommodation for
students. The equipment is in accordance with
most modern requirements for the efficient teaching
practice of Dental Surgery, including Radiology
Ultra-Violet Ray Therapy and a new department
Practical Pathology and Bacteriology. The
ations performed annually average 35,000, includ-
gold and other fillings, crowns, bridges, porcelain
vs, and injections for block and infiltration
sthesia. The orthodontic department is one of
foremost in the country. The Prosthetic and
anical Department is large and well lighted and
r a highly skilled instructor who is always
nt. Application for information as to fees and
larships must be sent to the Dean of the Medical
lty, Birmingham University, or the Dean of the
al Hospital, Birmingham.

eds University School of Dentistry.—The School of
istry is adequately equipped to provide for the
lete training of the dental student. A complete
ion of the course of training is in hand. The
ol forms a part of the Leeds School of Medicine,
t the instruction in clinical and mechanical
istry is carried out in the Dental Hospital at the
ral Infirmary. The School will shortly be housed
spacious new building especially designed to the
irements of modern dental teaching; it is anti-
ed that the building will be opened early in the
g of next year. The courses of study are mainly
ned to meet the requirements of the B.Ch.D.
L.D.S., Leeds, but every opportunity is afforded
tudents preparing for the degrees or diplomas
ther licensing bodies. Full-time demonstrators
the instruction in clinical dental surgery, pros-
c dentistry, and mechanics, which is carried out
r the supervision and direction of members of the
orary Staff, two of whom are in attendance each
Special facilities are provided for instruction
Orthodontia, Dental Radiography, Local and
ral Anæsthetics. Prizes are offered for competi-
to pupils and students in their respective years
udy. Communications should be addressed to
Warden, School of Dentistry, Leeds, from whom
ospectus may be obtained.

ntal Hospital of Manchester.—This hospital is in
iation for teaching purposes with the University
anchester and the Royal Infirmary, and is in
centre of a very large population. Courses of
y are provided to meet the requirements of the
us examining bodies, including those of the
ersity of Manchester for the qualifications L.D.S.
B.D.S., and the L.D.S. of the Royal College of
eons of England. Clinical instruction is given
ental Prosthetics, Operative Dentistry, Diagnosis
Extraction, Orthodontics, Dental Surgery, Radio-
hy, and Anæsthetics by specially appointed
cal Teachers.
l the courses of instruction are open to women
ents. Copies of the Prospectus will be forwarded
pplication to Mr. J. Hilditch Mathews, Dean.

ewcastle-upon-Tyne Dental Hospital and School.—
hospital is centrally situated (within five minutes
e various colleges, infirmary, and railway station);
ooms are well lighted and thoroughly equipped
arrying on the work. Dental surgeons and an
thetist attend each morning. A tutorial dental
on and a prosthetic tutor are also in attendance.
ls and Certificates of Merit are granted to
nts showing certain standards of proficiency
ie various classes at the Dental School. The
pectus of the Dental Hospital and School, con-
ng full information, may be obtained from
James Coltman, 13, Ellison-place, Newcastle-
-Tyne, Dean.

von and Exeter Dental Hospital, 24, Southernhay
, Exeter.—The hospital is open on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, and patients are admitted between the hours of 9.30 and 11 A.M. Students attend the practice of the hospital under the control of the medical officers. Secretary, Mr. Albert G. Littlejohn.

SCOTTISH TEACHING INSTITUTIONS.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street, and offers special advantages to dental students. A large and important extension of the existing buildings has now been opened. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital, 158, Renfrew-street and 15, Dalhousie-street, Glasgow.—The School is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, Radiology, Anæsthetics, and Dental Materia Medica. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extra-mural schools where special provision is made for Dental Students. A new mechanical laboratory with bench accommodation for 60 pupils and fully equipped with the most modern appliances for teaching practical dental mechanics has recently been added. Full information may be had on application to the Dean.

Glasgow Royal Infirmary (Dental Department).—The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. Clinical Medicine (three months) and Clinical Surgery (six months) are taken at the Royal Infirmary.

IRELAND.

Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.—All Dental Students who have passed their First Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy,

and Dental Materia Medica, and instruction in Anæsthetics. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

PRISON MEDICAL SERVICE.

CANDIDATES for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment may be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. In the smaller prisons the medical officership is part-time, and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer, Class II., and from the seniors of this rank the Medical Officers, Class I., are selected as vacancies occur. The pay of the whole-time prison medical staff is as follows: Medical Officer, Class II., £350, rising by annual increments of £20 to £600, making the pay at present with bonus £504 14*s.* to £801 11*s.*; Medical Officer, Class I., £650, rising by annual increments of £25 to £800, plus bonus, making the pay £864 to £1023 9*s.* Unfurnished quarters are provided or an allowance in lieu is made. Study leave is granted annually to two of the whole-time Medical Officers. There are 12 full-time medical officers of Class I. and 15 Class II., and 23 part-time medical officers. The number of vacancies is never large and promotion is slow.

THE DEATH OF MR. ALBAN DORAN.

WE announced last week that Mr. Alban Doran, the well-known anatomist and gynæcologist, was a patient in St. Bartholomew's Hospital. He was suffering from acute glaucoma in the only eye in which he still retained slight vision. We regret to say that on Tuesday last Mr. Doran died in the hospital in the 78th year of his age. The funeral is announced to take place in Kensal Green cemetery at noon to-day, Friday. Mr. Doran's death will be regretted by a large circle of friends and fellow workers. For nearly 60 years as anatomical student, gynæcological expert, and untiring literary researcher, he has been engaged in the practice of his profession with modest assiduity, and medical journalism has lost in him a valuable coöperator.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 13TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 127 (last week 172); scarlet fever, 1365 (last week 1234); diphtheria, 701; enteric fever, 74; pneumonia, 574; puerperal fever, 37; puerperal pyrexia, 93; cerebro-spinal fever, 4; acute poliomyelitis, 15; acute polio-encephalitis, 1; encephalitis lethargica, 35; continued fever, 1; dysentery, 4; ophthalmia neonatorum, 94. There was no case of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 19 (3) from measles, 4 (0) from scarlet fever, 15 (4) from whooping-cough, 20 (6) from diphtheria, 54 (10) from diarrhœa and enteritis under 2 years, and 26 (3) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths registered during the week was 239 in the great towns, including 48 from London.

Treasurer and Chairman of Council: C. M. FEGEN, M.R.C.S., L.R.C.P., D.P.H.
Trustees for the Reserve Fund:
Rt. Hon. LORD DAWSON, G.C.V.O., K.C.B., M.D., F.R.C.P. Sir ANTHONY A. BOWLBY, Bart., K.C.B., K.C.M.G., K.C.V.O., F.R.C.S. Sir HARRY BALDWIN, C.V.O., M.R.C.S., L.D.S.

The Society was founded for the following purposes: To protect, support, and safeguard the character and interests of legally qualified Medical and Dental Practitioners; to advise and assist Members of the Society in matters affecting their professional character and interests; and to indemnify them in regard to actions, etc., undertaken on their behalf.

SUBSCRIPTIONS. There is an Entrance Fee of 10s., and an Annual Subscription of £1.

The Invested Funds of the Society exceed £38,100. The Society is fully insured to an unlimited extent against all adverse costs and damages which may be awarded against Members in any action which the Society undertakes on their behalf.

Forms of application for Membership and full particulars may be obtained from the Secretaries at the above address.

NEW BOOKS

JUST PUBLISHED.

MALARIA IN INDIA

By SIR PATRICK HEHIR,
K.C.I.E., C.B., C.M.G., M.D., F.R.C.P.E., F.R.C.S.E., D.P.H.(Camb.), D.T.M.(Liverpool Univ.), I.M.S. (Retd.)

Pp. 510. 15 Coloured Plates. 108 Figs. 42/- net.

HEALTHY GROWTH

A study of the relation between the mental and physical development of adolescent boys in a public day school.

By ALFRED A. MUMFORD, M.D.
With a foreword by SIR ARTHUR KEITH, M.D., D.Sc., F.R.C.S.

368 Pages. 37 Illustrations. 16/- net.

The DIAGNOSIS of PANCREATIC DISEASE

By ROBERT COOPE, M.D., B.Sc., M.R.C.P.

Pp. 112. 5/- net.

THE TONGUE and its Diseases.

By D. C. L. FITZWILLIAMS, C.M.G., M.D., F.R.C.S.(Edin. & Eng.)

Pp. 528. 166 Illus. 6 Col. Plates. 36/- net.

A TEXTBOOK OF PSYCHIATRY

For Students and Practitioners.

By D. K. HENDERSON, M.D.(Edin.), F.R.F.P.S.(Glas.), and R. D. GILLESPIE, M.D.(Glas.), D.P.M.(Lond.)

Pp. 532. 18/- net.

THE EAR, NOSE and THROAT

in General Practice.

An informal Guide to the Main Principles.

By D. A. CROW, M.B., Ch.B.(Edin.)

Pp. 160. 2 Col. Plates. 4 Illus. 10/6 net.

THE THOMAS SPLINT

And its modifications in the Treatment of Fractures.

By MEURICE SINCLAIR C.M.G., M.B., Ch.B.(Edin.) With a foreword by Sir ROBERT JONES, K.B.E., C.B., F.R.C.S.

Pp. 182. 85 Illus., with X-Ray Photos. 3 Charts. 15/- net.

INTRACRANIAL TUMOURS, and some Errors in their Diagnosis. By Sir JAMES PURVES-STEWART, K.C.M.G., C.B., M.D.(Edin.), F.R.C.P. Pp.220. 51 Illus. **12/6** net.

AN ILLUSTRATED GUIDE TO THE SLIT LAMP. By T. HARRISON BUTLER, M.A., D.M.(Lond.), M.R.C.S.(Eng.), L.R.C.P.(Lond.) Pp.158. 5 Col. Plates. 158 Illus. **30/-** net.

DISEASES OF THE NEWBORN. A Textbook for Students and Practitioners. By JAMES BURNET, M.A., M.D., F.R.C.P.(Edin.) Pp. 286. **6/-** net.

THERAPEUTIC MALARIA. By G. de M. RUDOLF, M.R.C.S., L.R.C.P., D.P.H., D.P.M. Pp. 234. 2 Col. Plates. 55 Figs. **12/6** net.

CHRONIC RHEUMATIC DISEASES. Their Diagnosis and Treatment. By F. G. THOMSON, M.A.(Cantab.), M.D., F.R.C.P.(Lond.), and R. G. GORDON, M.D., B.Sc., M.R.C.P.(Edin.) Pp. 210. **8/6** net.

An Address
ON
ARWIN'S THEORY OF MAN'S DESCENT AS IT STANDS TO-DAY.

ing the Presidential Address delivered before the British Association for the Advancement of Science, Leeds Meeting, August 31st, 1927,

Y PROF. SIR ARTHUR KEITH, M.D. ABERD., D.Sc., LL.D., F.R.S.

Sir Arthur Keith prefaced his address with a ssage to the Prince of Wales in which he stated t the interest His Royal Highness had taken, ilst President last year, in the work of the ociation would prove a permanent source of ouragement for all who work for the betterment fe through increase of knowledge. He proceeded:—]

he subject of my address is Man's remote history. ty-five years have come and gone since Charles rwin wrote a history of Man's Descent. How does work stand the test of time? This is the question ropose to discuss.

THE OPENING SHOT IN THE DARWINIAN BATTLE.

n tracing the course of events which led up to present conception of man's origin, no place could ve as a historical starting-point so well as Leeds. this city was fired the first verbal shot of that long t bitter strife which ended in the overthrow of se who defended the Biblical account of man's ation and in a victory for Darwin. On Sept. 24th, 8—69 years ago—the British Association assembled this city just as we do to-night; Sir Richard en, the first anatomist of his age, stood where ow stand. He had prepared a long address and veyed, as he was well qualified to do, the whole lm of science; but only those parts which concern n's origin require our attention now. He cited dence which suggested a much earlier date for the earance of man on earth than was sanctioned by lical records, but poured scorn on the idea that n was merely a transmuted ape. He declared to assembled Association that the differences between n and ape were so great that it was necessary, in opinion, to assign mankind to an altogether arate order in the animal kingdom. As this ement fell from the President's lips there was least one man in the audience whose spirit of osition was roused—Thomas Henry Huxley—en's young and rising antagonist.

OWEN AND HUXLEY.

have picked out Huxley from the audience ause it is necessary for the development of my me that we should give him our attention for moment. We know what Huxley's feelings were ards Owen at the date of the Leeds meeting. months before he had told his sister that "an rnecine feud rages between Owen and myself," on the eve of his departure for Leeds he wrote to ker: "The interesting question arises: Shall I e a row with the great O. there?" I am glad to the Leeds meeting passed off amicably, but it led in Huxley's mind what the "row" was to be ut when it came. It was to concern man's rightful ition in the scale of living things.

MAN'S POSITION IN THE ANIMAL KINGDOM.

wo years later, in 1860, when this Association in Oxford, Owen gave Huxley the opportunity desired. In the course of a discussion Owen eated the statement made at Leeds as to man's arate position, claiming that the human brain had ain structural features never seen in the brain of hropoid apes. Huxley's reply was a brief and emphatic denial with a promise to produce evidence in due course—which was faithfully kept. This opening passage at arms between our protagonists was followed two days later by that spectacular fight—the most memorable in the history of our Association—in which the Bishop of Oxford, the representative of Owen and of orthodoxy, left his scalp in Huxley's hands. To make his victory decisive and abiding, Huxley published, early in 1863, "The Evidences of Man's Place in Nature," a book which has a very direct bearing on the subject of my discourse. It settled for all time that man's rightful position is among the primates, and that as we anatomists weigh evidence, his nearest living kin are the anthropoid apes.

OWEN'S OPINION OF DARWINISM.

My aim is to make clear to you the foundations on which rest our present-day conception of man's origin. The address delivered by my predecessor from this chair at the Leeds meeting of 1858 has given me the opportunity of placing Huxley's fundamental conception of man's nature in a historical setting. I must now turn to another issue which Sir Richard Owen merely touched upon but which is of supreme interest to us now. He spent the summer in London, just as I have done, writing his address for Leeds and keeping an eye on what was happening at scientific meetings. In his case something really interesting happened. Sir Charles Lyell and Sir Joseph Hooker left with the Linnean Society what appeared to be an ordinary roll of manuscript, but what in reality was a parcel charged with high explosives, prepared by two very innocent-looking men—Alfred Russel Wallace and Charles Darwin. As a matter of honesty it must be admitted that these two men were well aware of the deadly nature of its contents, and knew that if an explosion occurred, man himself, the crown of creation, could not escape its destructive effects. Owen examined the contents of the parcel and came to the conclusion that they were not dangerous; at least, he manifested no sign of alarm in his Presidential Address. He dismissed both Wallace and Darwin, particularly Darwin, in the briefest of paragraphs, at the same time citing passages from his own work to prove that the conception of natural selection as an evolutionary force was one which he had already recognised.

THE TRANSFORMATION OF OUR OUTLOOK ON MAN'S ORIGIN.

I cannot help marvelling over the difference between our outlook to-day and that of the audience which Sir Richard Owen had to face in this city 69 years ago. The vast assemblage which confronted him was convinced, almost without a dissentient, that man had appeared on earth by a special act of creation; whereas the audience which I have now the honour of addressing, and that larger congregation which the wonders of wireless bring within the reach of my voice, if not convinced Darwinists are yet prepared to believe, when full proofs are forthcoming, that man began his career as a humble primate animal, and has reached his present estate by the action and reaction of biological forces which have been and are ever at work within his body and brain.

DARWIN'S GENERALSHIP.

This transformation of outlook on man's origin is one of the marvels of the nineteenth century, and to see how it was effected we must turn our attention for a little while to the village of Down in the Kentish uplands and note what Charles Darwin was doing on the very day that Sir Richard Owen was delivering his address here in Leeds. He sat in his study struggling with the first chapter of a new book; but no one foresaw, Owen least of all, that the publication of the completed book, "The Origin of Species," 15 months later (1859) was to effect a sweeping revolution in our way of looking at living things and to initiate a new period in human thought—the

Darwinian period—in which we still are. Without knowing it, Darwin was a consummate general. He did not launch his first campaign until he had spent 22 years in stocking his arsenal with ample stores of tested and assorted fact. Having won territory with "The Origin of Species," he immediately set to work to consolidate his gains by the publication in 1868 of another book, "The Variation of Animals and Plants under Domestication"—a great and valuable treasury of biological observation. Having thus established an advanced base, he moved forwards on his final objective—the problem of human beginnings—by the publication of "The Descent of Man" (1871), and that citadel capitulated to him. To make victory doubly certain he issued in the following year—1872—"The Expression of the Emotions in Man and Animals." Many a soldier of truth had attempted this citadel before Darwin's day, but they failed because they had neither his generalship nor his artillery.

History as Written by Darwin.

Will Darwin's victory endure for all time? Before attempting to answer this question, let us look at what kind of book "The Descent of Man" is. It is a book of history—the history of man, written in a new way—the way discovered by Charles Darwin. Permit me to illustrate the Darwinian way of writing history. If a history of the modern bicycle had to be written in the orthodox way, then we should search dated records until every stage was found which linked the two-wheeled hobby-horse, bestrode by tall-hatted fashionable men at the beginning of the nineteenth century, to the modern "jeopardy" which now flashes past us in country lanes. But suppose there were no dated records—only a jumble of antiquated machines stored in the cellar of a museum. We should, in this case, have to adopt Darwin's way of writing history. By an exact and systematic comparison of one machine with another we could infer the relationship of one to another and tell the order of their appearance, but as to the date at which each type appeared and the length of time it remained in fashion, we could say very little. It was by adopting this circumstantial method that Darwin succeeded in writing the history of man. He gathered historical documents from the body and behaviour of man and compared them with observations made on the body and behaviour of every animal which showed the least resemblance to man. He studied all that was known in his day of man's embryological history and noted resemblances and differences in the corresponding histories of other animals. He took into consideration the manner in which the living tissues of man react to disease, to drugs, and to environment; he had to account for the existence of diverse races of mankind. By a logical analysis of his facts Darwin reconstructed and wrote a history of man.

Darwin's Impregnable Position: Evidence of Fossil Remains.

Fifty-six years have come and gone since that history was written; an enormous body of new evidence has poured in upon us. We are now able to fill in many pages which Darwin had perforce to leave blank, and we have found it necessary to alter details in his narrative, but the fundamentals of Darwin's outline of man's history remain unshaken. Nay, so strong has his position become that I am convinced that it never can be shaken.

Why do I say so confidently that Darwin's position has become impregnable? It is because of what has happened since his death in 1882. Since then we have succeeded in tracing man by means of his fossil remains and by his stone implements backwards in time to the very beginning of that period of the earth's history to which the name Pleistocene is given. We thus reach a point in history which is distant from us at least 200,000 years, perhaps three times that amount. Nay, we have gone farther, and traced him into the older and longer period which preceded the Pleistocene—the Pliocene. It was in strata laid down by a strea in Java during the latter part of the Pliocene peri that Dr. Eugene Dubois found, ten years aft Darwin's death, the fossil remains of that remarkal representative of primitive humanity to which gave the name *Pithecanthropus*, or ape-man; fro Pliocene deposits of East Anglia Mr. Reid Moir h recovered rude stone implements. If Darwin w right, than as we trace man backwards in the sca of time he should become more bestial in form—near to the ape. That is what we have found. But we regard *Pithecanthropus* with his small and simp yet human brain as a fair representative of the m of the Pliocene period, then evolution must ha proceeded at an unexpectedly rapid rate to culmina to-day in the higher races of mankind.

Man's Descent has not been in a Straight Lin

The evidence of man's evolution from an ape-li being, obtained from a study of fossil remains, definite and irrefutable, but the process has be infinitely more complex than was suspected in Darwir time. Our older and discarded conception of mar transformation was depicted in that well-knov diagram which showed a single file of skeletons, t gibbon at one end and man at the other. In o original simplicity we expected, as we traced m backwards in time, that we should encounter graded series of fossil forms—a series which wou carry him in a straight line towards an anthropo ancester. We should never have made this initi mistake if we had remembered that the guide to t world of the past is the world of the present. In o time man is represented not by one but by many ar diverse races—black, brown, yellow, and white; son of these are rapidly expanding, others are as rapid disappearing. Our searches have shown that remote times the world was peopled, sparsely it true, with races showing even a greater diversity tha those of to-day, and that already the same process replacement was at work. To unravel man's pedigr we have to thread our way, not along the links of chain, but through the meshes of a complicate network.

Diversity of Form in Ancient Times.

We made another mistake. Seeing that in o search for man's ancestry we expected to reach a age when the beings we should have to deal with wou be simian rather than human, we ought to have mark the conditions which prevail amongst living anthropo apes. We ought to have been prepared to find, a we approached a distant point in the geologic horizon, that the forms encountered would be widely different as are the gorilla, chimpanzee, ar orang, and confined, as these great anthropoi now are, to limited parts of the earth's surface. Tha is what we are now realising; as we go backwar in time we discover that mankind becomes broken u not into separate races as in the world of to-da but into numerous and separate species. When w go into a still more remote past they become s unlike that we have to regard them not as belongin to separate species but different genera. It is among this welter of extinct fossil forms which strew th ancient world that we have to trace the zigzag lin of man's descent. Do you wonder we sometime falter and follow false clues?

Discordant Evolution.

We committed a still further blunder when w set out on the search for man's ancestry; indeed, som of us are still making it. We expected that man evolution would pursue not only an orderly file stages but that every part of his body—skull, brai jaws, feet, skin, body, arms, and legs—would a each stage become a little less ape-like, a little mor man-like. Our searches have shown us that man evolution has not proceeded in this orderly manne In some extinct races, while one part of the bod has moved forwards another part has lagged behin Let me illustrate this point, because it is important

We now know that, as Darwin sat in his study at Down, there lay hidden at Piltdown, in Sussex, not 10 miles distant from him, sealed up in a bed of gravel, a fossil human skull and jaw. In 1912, 10 years after Darwin's death, Mr. Charles Dawson discovered this skull, and my friend Sir Arthur Smith Woodward described it, and rightly recognised that skull and jaw were parts of the same individual, and that this individual had lived, as was determined by geological and other evidence, in the opening phase of the Pleistocene period. We may confidently presume that this individual was representative of the people who inhabited England at this remote date. The skull, although deeply mineralised and thick-walled, might well have been the rude forerunner of a modern skull, but the lower jaw was so ape-like that some experts denied that it went with the human fossil skull at all, and supposed it to be the lower jaw of some extinct kind of chimpanzee. This mistake would never have been made if those concerned had studied the comparative anatomy of anthropoid apes. Such a study would have prepared them to meet with the disordances of evolution. The same irregularity in the progression of parts is evident in the anatomy of *Pithecanthropus*, the oldest and most primitive form of humanity so far discovered. The thigh-bone might easily be that of modern man, the skull-cap that of an ape, but the brain within that cap, as we now know, had passed well beyond an anthropoid status. If merely a lower jaw had been found at Piltdown an ancient Englishman would have been wrongly labelled "higher anthropoid ape"; if only the thigh-bone of *Pithecanthropus* had come to light in Java, then an ancient Javanese, almost deserving the title of anthropoid, would have passed muster as a man.

Blanks Still Remain in the Geological Record.

Such examples illustrate the difficulties and dangers which beset the task of unravelling man's ancestry. There are other difficulties; there still remain great blanks in the geological record of man's evolution. As our search proceeds these blanks will be filled in, but in the meantime let us note their nature and their extent. By the discovery of fossil remains we have followed man backwards to the close of the Pliocene—a period which endured at least for a quarter of a million years, but we have not yet succeeded in tracing him through this period. It is true that we have found fossil teeth in Pliocene deposits which may be those of an ape-like man or of a man-like ape; until we find other parts of their bodies we cannot decide. When we pass into the still older Miocene period—one which was certainly twice as long as the Pliocene—we are in the heyday of anthropoid history. Thanks to the labours of Dr. Guy E. Pilgrim, of the Indian Geological Survey, we know already of a dozen different kinds of great anthropoids which lived in Himalayan jungles during middle and later Miocene times; we know of at least three other kinds of great anthropoids which lived in the contemporary jungles of Europe. Unfortunately, we have found as yet only the most resistant parts of their bodies—teeth and fragments of jaw. Do some of these fragments represent a human ancestor? We cannot decide until a lucky chance brings to light a limb-bone or a piece of skull, but no one can compare the teeth of these Miocene anthropoids with those of primitive man, as has been done so thoroughly by Prof. William K. Gregory, and escape the conviction that in the dentitions of the extinct anthropoids of the Miocene jungles we have the ancestral forms of human teeth.

Date of Man's Emergence.

It is useless to go to strata still older than the Miocene in search of man's emergence; in such strata we have found only fossil traces of emerging anthropoids. All the evidence now at our disposal supports the conclusion that man has arisen, as Lamarck and Darwin suspected, from an anthropoid ape not higher in the zoological scale than a chimpanzee, and that the date at which human and anthropoid lines of descent began to diverge lies near the beginning of the Miocene period. On our modest scale of reckoning, that gives man the respectable antiquity of about one million years.

Proofs of our Anthropoid Ancestry.

Our geological search, which I have summarised all too briefly, has not produced so far the final and conclusive evidence of man's anthropoid origin; we have not found as yet the human *imago* emerging from its anthropoid encasement. Why, then, do modern anthropologists share the conviction that there has been an anthropoid stage in our ancestry? They are no more blind than you are to the degree of difference which separates man and ape in structure, in appearance, and in behaviour. I must touch on the sources of this conviction only in a passing manner. Early in the present century Prof. G. H. F. Nuttall, of Cambridge University, discovered a trustworthy and exact method of determining the affinity of one species of animal to another by comparing the reactions of their blood. He found that the blood of man and that of the great anthropoid apes gave almost the same reaction. Bacteriologists find that the living anthropoid body possesses almost the same susceptibilities to infections, and manifests the same reactions, as does the body of man. So alike are the brains of man and anthropoid in their structural organisation that surgeons and physiologists transfer experimental observations from the one to the other. When the human embryo establishes itself in the womb it throws out structures of a most complex nature to effect a connexion with the maternal body. We now know that exactly the same elaborate processes occur in the anthropoid womb and in no other. We find the same vestigial structures—the same "evolutionary post-marks"—in the bodies of man and anthropoid. The anthropoid mother fondles, nurses, and suckles her young in the human manner. This is but a tithe of the striking and intimate points in which man resembles the anthropoid ape. In what other way can such a myriad of coincidences be explained except by presuming a common ancestry for both?

Evolution of Man's Brain.

The crucial chapters in Darwin's "Descent of Man" are those in which he seeks to give a historical account of the rise of man's brain and of the varied functions which that organ subserves. How do these chapters stand to-day? Darwin was not a professional anatomist, and therefore accepted Huxley's statement that there was no structure in the human brain that was not already present in that of the anthropoid. In Huxley's opinion the human brain was but a richly annotated edition of the simpler and older anthropoid book, and that this edition, in turn, was but the expanded issue of the still older original primate publication. Since this statement was made thousands of anatomists and physiologists have studied and compared the brain of man and ape; only a few months ago Prof. G. Elliot Smith summarised the result of this intensive inquiry as follows: "No structure found in the brain of an ape is lacking in the human brain, and, on the other hand, the human brain reveals no formation *of any sort* that is not present in the brain of the gorilla or chimpanzee. . . . The only distinctive feature of the human brain is a quantitative one." The difference is only quantitative but its importance cannot be exaggerated. In the anthropoid brain are to be recognised all those parts which have become so enormous in the human brain. It is the expansion of just those parts which has given man his powers of feeling, understanding, acting, speaking, and learning.

Evidence of Psychology.

Darwin himself approached this problem not as an anatomist but as a psychologist, and after many years of painstaking and exact observation succeeded

in convincing himself that, immeasurable as are the differences between the mentality of man and ape, they are of degree, not of kind. Prolonged researches made by modern psychologists have but verified and extended Darwin's conclusions. No matter what line of evidence we elect to follow—evidence gathered by anatomists, by embryologists, by physiologists, or by psychologists—we reach the conviction that man's brain has been evolved from that of an anthropoid ape, and that in the process no new structure has been introduced and no new or strange faculty interpolated.

UNEXPLAINED PROBLEMS.

In these days our knowledge of the elaborate architecture and delicate machinery of the human brain makes rapid progress, but I should mislead if I suggested that finality is in sight. Far from it; our inquiries are but begun. There is so much we do not yet understand. Will the day ever come when we can explain why the brain of man has made such great progress while that of his cousin the gorilla has fallen so far behind? Can we explain why inherited ability falls to one family and not to another, or why, in the matter of cerebral endowment, one race of mankind has fared so much better than another? We have as yet no explanation to offer, but an observation made 20 years ago by one on whom nature has showered great gifts—a former President of this Association and the doyen of British zoologists, Sir E. Ray Lankester—deserves quotation in this connexion: "The leading feature in the development and separation of man from other animals is undoubtedly the relative enormous size of the brain in man and the corresponding increase in its activities and capacity. It is a striking fact that it was not in the ancestors of man alone that this increase in the size of the brain took place at this same period—the Miocene. Other great mammals of the early Tertiary period were in the same case." When primates made their first appearance in geological records they were, one and all, small-brained. We have to recognise that the tendency to increase of brain, which culminated in the production of the human organ, was not confined to man's ancestry but appeared in diverse branches of the mammalian stock at a corresponding period of the earth's history.

DARWIN'S CONCEPTION OF EVOLUTION ILLUSTRATED.

I have spoken of Darwin as a historian. To describe events and to give the order of their occurrence is the easier part of a historian's task; his real difficulties begin when he seeks to interpret the happenings of history, to detect the causes which produced them, and explain why one event follows as a direct sequel to another. Up to this point we have been considering only the materials for man's history, and placing them, so far as our scanty information allows, in the order of their sequence, but now we have to seek out the biological processes and controlling influences which have shaped the evolutionary histories of man and ape. The evolution of new types of man or of ape is one thing, and the evolution of new types of motor-cars is another, yet for the purposes of clear thinking it will repay us to use the one example to illustrate the other. In the evolution of motor vehicles Darwin's law of selection has prevailed; there has been severe competition, and the types which have answered best to the needs and tastes of the public have survived. The public has selected on two grounds—first for utility, thus illustrating Darwin's law of natural selection, and secondly because of appearance's sake; for, as most people know, a new car has to satisfy not only the utilitarian demands of its prospective master but also the æsthetic tastes of its prospective mistress, therein illustrating Darwin's second law—the law of sexual selection. That selection, both utilitarian and æsthetic, is producing an effect on modern races of mankind and in surviving kinds of ape, as Darwin supposed, cannot well be questioned. In recent centuries the inter-racial competition amongst men for the arable lands of the world is keener than in any known period of hum history.

PRODUCTION OF NEW TYPES.

The public has selected its favoured types of c but it has had no direct hand in designing and p ducing modifications and improvements which ha appeared year after year. To understand how su modifications are produced the inquirer must enter factory and not only watch artisans shaping a fitting parts together but also visit the designer's offic In this way an inquirer will obtain a glimpse of t machinery concerned in the evolution of motor-ca If we are to understand the machinery which underli the evolution of man and of ape, we have to enter t "factories" where they are produced—look with the womb and see the ovum being transformed in an embryo, the embryo into a fœtus, and the fœt into a babe. After birth we may note infancy passi into childhood, childhood into adolescence, adolescen into maturity, and maturity into old age. Merely register the stages of change is not enough; to unde stand the controlling machinery we have to sear out and uncover the processes which are at wo within developing and growing things and the influenc which coördinate and control all the processes of develo ment and of growth. When we have discovered t machinery of development and of growth we sh also know the machinery of evolution, for they a the same.

MACHINE AND ANIMAL EVOLUTION CONTRASTED.

If the simile I have used would sound strange Darwin's ear could he hear it, the underlying meani would be familiar to him. Over and over again declared that he did not know how "variations were produced, favourable or otherwise; nor cou he have known, for in his time hormones were undream of and experimental embryology scarcely born. Wi these recent discoveries new vistas opened up f students of evolution. The moment we begin work out the simile I have used and compare t evolutionary machinery in a motor factory with th which regulates the development of an embryo with the womb, we realise how different the two process are. Let us imagine for a moment what chang would be necessary were we to introduce "embry logical processes" into a car factory. We have conceive a workshop teeming with clustering swarn of microscopic artisans, mere specks of living matte In one end of this factory we find swarms busy wi cylinders, and as we pass along we note that eve part of a car is in process of manufacture, each pa being the business of a particular brigade of micr scopic workmen. There is no apprenticeship in th factory, every employee is born, just as a hiv bee is, with his skill already fully developed. N plans or patterns are supplied; every workman h the needed design in his head from birth. There neither manager, overseer, nor foreman to dire and coördinate the activities of the vast artisan armie And yet if parts are to fit when assembled, if pinio are to mesh and engines run smoothly, there mu be some method of coördination. It has to be method plastic enough to permit difficulties to overcome when such are encountered and to perm the introduction of advantageous modificatio when these are needed. A modern works manag would be hard put to it were he asked to devise a automatic system of control for such a factory, y it is just such a system that we are now obtainir glimpses of in the living workshops of nature.

MACHINERY OF DEVELOPMENT.

I have employed a crude simile to give the la mind an inkling of what happens in that "factory where the most complicated of machines are forg —the human body and brain. The fertilised ovu divides and redivides; one brood of microscop living units succeeds another, and as each is produc the units group themselves to form the "parts" an embryo. Each "part" is a living society; t

nbryo is a huge congeries of interdependent societies. ow are their respective needs regulated, their freedoms otected, and their manœuvres timed? Experimental nbryologists have begun to explore and discover the achinery of regulation. We know enough to realise at it will take many generations of investigators work over the great and new field which is thus ening up. When this is done we shall be in a better sition to discuss the cause of "variation" and the achinery of evolution.

MACHINERY OF GROWTH.

If we know only a little concerning the system of vernment which prevails in the developing embryo e can claim that the system which prevails in the owing body, as it passes from infancy to maturity, becoming better known to us every year. The fluence of the sex glands on the growth of the body as been known since ancient times; their removal youth leads to a transformation in the growth of very part of the body, altering at the same time ie reactions and temperament of the brain. In ore recent years medical men have observed that aracteristic alterations in the appearance and nstitution of the human body can be produced by ie action of other glands—the pituitary, thyroid, arathyroid, and adrenals. Under the disorderly tion of one or other of these glands individuals may, the course of a few years, take on so changed an pearance that the differences between them and eir fellows become as great as, or even greater than, ose which separate one race of mankind from nother. The physical characters which are thus tered are just those which mark one race off from nother. How such effects are produced we did not now until 1904, when the late Prof. E. H. Starling, leader amongst the great physiologists of our time, id bare an ancient and fundamental law in the living nimal body—his law of hormones. I have pictured ie body of a growing child as an immense society ade up of myriads of microscopic living units, ever creasing in numbers. One of the ways—probably ie oldest and most important way—in which the ctivities of the communities of the body are coördinted and regulated is by the postal system discovered y Starling, wherein the missives are hormones—hemical substances in ultra-microscopic amounts, espatched from one community to another in the irculating blood. Clearly the discovery of this ncient and intricate system opens up fresh vistas o the student of man's evolution. How Darwin ould have welcomed this discovery! It would have iven him a rational explanation to so many of his nsolved puzzles, including that of "correlated ariations." Nor can I in this connexion forbear to ention the name of one who presided so ably over he affairs of this Association 15 years ago—Sir E. harpey-Schafer. He was the pioneer who opened p this field of investigation, and has done more than nyone to place our knowledge of the nature and ction of the glands of internal secretion on a precise asis of experimental observation. With such sources f knowledge being ever extended and others of great mportance, such as the study of heredity, which have een left unmentioned, we are justified in the hope that nan will be able in due time not only to write his own istory but to explain how and why events took the ourse they did.

Briefly I have attempted to answer a question of momentous importance to all of us—What is man's rigin? Was Darwin right when he said that man, nder the action of biological forces which can be bserved and measured, has been raised from a place mongst anthropoid apes to that which he now ccupies? The answer is Yes! and in returning his verdict I speak but as foreman of the jury—a jury which has been empannelled from men who have levoted a lifetime to weighing the evidence. To the best of my ability I have avoided, in laying before you the evidence on which our verdict was found, he rôle of special pleader, being content to follow Darwin's own example—Let the truth speak for itself.

A CASE OF
MALIGNANT LYMPHADENOSIS,
WITH SOME REMARKS ON LEUKÆMIC DISEASES IN GENERAL.

BY T. VINCENT DICKINSON, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE ITALIAN HOSPITAL
AND
HENRY LWOW, M.D. VIENNA, L.R.C.P. EDIN.,
RESIDENT MEDICAL OFFICER TO THE HOSPITAL.

THE great variety of symptoms met with in diseases of leukæmic type sometimes makes it very difficult to fit a case of this kind into a certain group according to the usual classification. Since Virchow and John Hughes Bennett described leukæmia as distinct from leucocytosis and pyæmia, authors in different countries when publishing their cases have tried to assort their observations into a multitude of new groups. Thus we find in the literature on the subject a legion of diseases which very often indeed are indistinguishable from each other and which not always bear happily chosen terms. The reason of this confusing classification lies not only in the obscure ætiology of the disease, but also in the variable relations between the clinical history, the condition of the blood, and the histological picture of the organs affected. The as yet unsettled origin of blood-cells makes a clear classification still more difficult.

The early authors considered the disease merely as a pathological condition of the blood, and the changes in the organs were looked upon as the result of a secondary spread of pathological cells from the blood. The pathological blood-picture was thus regarded as an essential part of the disease. Hence the term leukæmia or leukocythæmia. When Cohnheim and, later, Pinkus described a condition which corresponded clinically and histologically with the usual type of leukæmia, but without the changes in the blood, they called it pseudoleukæmia, still apparently under the impression that there could be no true leukæmia without a definite pathological blood-picture.

Since then we have learned to regard the histological picture of the organs affected as most characteristic of the disease, and the leukæmic condition of blood only as a frequent though not essential symptom for diagnosis. We know now that leukæmia and some allied diseases represent a systemic affection of the hæmatopoietic tissue, which is scattered all over the organism. The histological organic changes are due to a proliferation *in situ* originating from undifferentiated perivascular and connective tissue cells, upon which groups of cells especially Ferrata's researches in recent years have thrown some light.

As long as the mystery of the primary cause of this abnormal proliferation remains unsolved, the most important guiding points in the classification of these diseases should therefore be the appearance of the histological picture of different organs. If we adopt this point of view, terms like pseudoleukæmia or even leukæmia will appear to be very unscientific. The term pseudoleukæmia, which is still used by many authors, is particularly misleading. Some authors,[1] like Rieux, include in this group even such diseases as Hodgkin's or Gaucher's splenomegaly. Pappenheim,[2] like many other German authors, divides diseases of the hæmatopoietic system into two main groups: (1) generalised leucocytomatosis; (2) generalised granulomatosis. To use Pappenheim's own words:—

> "The histological difference between the leucocytomatous (myeloid and lymphadenoid) and granulomatous forms seems to be that in the first case there is a proliferation of the myeloid and myelopotential, or lymphadenoid and lymphopotential, parenchyma, while in the case of the granulomatosis there is a proliferation of the interparenchymatous stroma, with a tendency to scar tissue formation and sclerosis."

Thus to the category "granulomatosis" would belong Hodgkins' disease and all the generalised inflammatory diseases of lymphatic glands—i.e., of tuberculous or syphilitic nature, Banti's disease, &c.

To the other group belong all the varieties of leukæmias. This group is subdivided by Pappenheim, Rieux, Clerc,[3] and others in a very similar way to each other. The difference lies more with the nomenclature. The most popular classification is into: (1) lymphadenosis, corresponding with lymphatic leukæmia; and (2) myelosis (Schridde), identical with myeloid leukæmia. Each of them may have a leukæmic or an aleukæmic blood-picture. And, according to Rieux, each of them may be of a benign or malignant type, and may be localised or generalised. We may thus meet with a benign generalised leukæmic lymphadenosis, which would correspond with the term lymphatic leukæmia, or in another case we may find a localised malignant aleukæmic lymphadenosis, which would correspond with Kundrat-Paltauf's lymphosarcoma; and in fact all possible combinations may be met with.

The advantage of this terminology is, that (1) it emphasises the histological changes in the tissues; (2) shows the common nature of all these diseases, and (3) shows that there are no clear limits between them—i.e., one type may pass into another during the course of the disease. A case we had recently the opportunity of observing gives, in our opinion, quite a good illustration of the relationship between these groups.

History of the Case.

The patient, A. B., an Italian shopkeeper, aged 40, was admitted to the Italian Hospital on March 13th, 1927. He was a tall, fairly well nourished and strongly built man. He complained of pain in the left side for the last three weeks. He had suffered previously from cough every winter, from frequent indigestion and lassitude. There had been no other previous illnesses. On examination the face and mucous membranes were found to be pale. Temperature, pulse, respiration were normal. Blood pressure 120/90.

The left hypochondrium was rigid and very tender, and a hard tumour could be felt occupying the whole of the left hypochondriac and partly the epigastric region, with a hard edge three fingers below the left costal margin. No notch could be felt, and the tumour did not move on respiration. It was continuous across the abdomen with the edge of the right lobe of the liver, which reached three fingers below the right costal margin.

The patient had noticed the swelling only for three weeks. Lungs: the left base was dull and some friction could be heard. Right upper lobe showed diminished air entry. The sputum contained pneumococci and streptococci; no tubercle bacilli. The heart was pushed over to the right and upwards. An X ray picture showed the left dome of diaphragm greatly pushed upwards.

Lymph glands, cervical, axillary, inguinal, and femoral, very large, discrete, and freely movable. Some of the cervical glands were as large as a pigeon's egg. Tonsils not enlarged. Per rectum some very large glands could be felt at the bifurcation of the aorta. The patient stated that he had had all these enlarged glands for many years, but he was not quite certain if some of them had increased in size lately. His medical attendant told us that the patient had these enlarged glands as far back as ten years ago, when he came to him for some gastric trouble and wanted to have a large cervical gland removed. There was, however, no blood-count made at this time.

Urine contained a trace of albumin, no casts, a few *B. coli*. The blood-count made on March 18th gave normal figures: 8200 white cells and a normal differential count. 20th: The spleen now reached the umbilicus. 21st: A cervical lymphatic gland was excised for a biopsy: it was grey in appearance and of a very soft consistency; microscopically it showed absence of the usual lymph gland structure with its regeneration centres. There was but little stroma and a few vessels were seen. It consisted of a uniform mass of cells having the appearance of small lymphocytes packed tightly within the capsule and compressed near the periphery. Amongst them there were scattered some cells showing mitosis and a few endothelial cells. Wassermann reaction was negative. A couple of days later the throat became dry and inflamed. Some ecchymosis were seen on the palate and back of tongue.

The patient had a severe epistaxis on March 25th. An examination of blood made on the 28th showed red cells 4,810,000, hæmoglobin 90 per cent., white cells 6500; differential count: lymphocytes (the majority being of the small type) 45 per cent., segmented neutrophiles 35 per cent., myelocytes 4 per cent., young metamyelocytes 2 per cent., neutrophiles with a rod-shaped nucleus 10 per cent., basophiles 3 per cent., eosinophiles 1 per cent. On the 29th another differential count was made showing neutrophiles 65 per cent., lymphocytes 33 per cent., hyalines 2 per cent.

The abdomen became now more and more distended. On March 30th the liver reached a line from the right iliac spine to the umbilicus. There was evidence of free fluid in the abdominal cavity. On the 29th the temperature, which till then had not risen above 99·4° in the evening, went up to 100·6°, but came down again to 98° on the 31st.

A differential count on April 2nd gave neutrophiles 25 per cent., large lymphocytes 20 per cent., small lymphocytes 35 per cent., hyalines 4 per cent., eosinophiles 1 per cent., myelocytes 5 per cent., metamyelocytes 5 per cent., lymphoblasts 5 per cent. Platelets 220,000 per c.cm., red cells normal. Œdema of both legs, probably due to pressure, appeared on April 5th. Patient complained of very much abdominal pain.

On April 7th another examination of blood showed: red cells 4,600,000, hæmoglobin 90 per cent., white cells 60,000, differential count: small lymphocytes 70½ per cent., large lymphocytes 15½ per cent., lymphoblasts 1½ per cent., segmented neutrophiles 2½ per cent., neutrophiles with rod-shaped nuclei 4½ per cent., myelocytes 1 per cent., metamyelocytes 4½ per cent.

The general condition of the patient became now rapidly worse. On April 16th he had a severe rectal hæmorrhage. An examination of blood done the same day gave red cells 4,120,000, hæmoglobin 75 per cent., anisocytosis and poikilocytosis. White cells 68,400, small lymphocytes 89½ per cent., large 7 per cent., myelocytes ½ per cent., metamyelocytes 2 per cent., segmented neutrophiles 1 per cent. On the 17th the patient had another rectal hæmorrhage, and he died in the evening of the same day. The temperature went up shortly before death to 100·8°, this being the highest noted temperature during the patient's stay at the hospital.

Necropsy.—In the thorax: there was a chain of large glands in the mediastinum. They were all soft, of a putty-like consistency. There were several infiltrations of a similar character in the wall of the thorax and on the diaphragm. Lungs: nothing abnormal. Heart: dilated and showing myocardial degeneration. Left dome of diaphragm pushed very much upwards by the spleen. Abdomen: free fluid present. Spleen weighed 8½ lb. and was of hard consistency. There were signs of a perisplenitis. The section showed on a dark brown background large, irregular, confluent, grey patches. Several smaller and larger infarcts were present.

The liver weighed 9¼ lb. On section it had greyish irregular patches of different sizes. The posterior wall of the stomach contained a round patch of infiltration which unfortunately was overlooked at the microscopical examination. The kidneys did not show anything abnormal on naked-eye examination. There were enlarged lymph glands forming huge confluent masses between the pancreas and the stomach. Some of them were larger than a man's fist. Glands in other situations were considerably enlarged. The bone marrow of the right humerus, which was sawn open longitudinally, was found to be of dark red colour.

Microscopic Examination.—Lymph glands showed the same structure as that described above in the biopsy. The spleen was packed with a mass of cells uniform in character and of the same appearance as in lymph glands and other organs. They were of the size of a small lymphocyte with a darkly staining nucleus and a narrow rim of cytoplasm. There was only some scanty necrotic spleen pulp present. The liver showed a marked interacinous infiltration with the same type of cell. There were also large islands of packed masses of these cells present. Kidney: Sections showed an infiltration around the tubules, and there were also small masses of cells of the same character. Bone marrow consisted of a crowded uniform mass of cells as described above. Amongst them there were only a few erythroblasts and some fat tissue.

Discussion.

Dr. Knyvett Gordon, who kindly examined for us some sections, expressed his opinion that in view of the uniformity of cells he would regard it as lymphosarcoma. Dr. Parkes Weber, to whom we are very much indebted for his keen interest in the case, thought it to be a case of lymphatic leukæmia. In our opinion these two views are not contradictory, but lend support to our conception regarding the relationship between lymphosarcoma and leukæmia.

The patient had a generalised enlargement of glands for very many years. We assume that it was a case of benign aleukæmic lymphadenosis. The

blood-picture when we first saw him was still normal. The histological picture of the gland dissected in vivo excluded the possibility of a previous existence of Hodgkin's disease. Such cases with an acute "poussée" are met with frequently in literature, but they are generally characterised by the appearance of large cells in the tissues and in the blood.

The most striking feature of this case was the uniformity of small lymphocytes found in all organs, and in the mediastinal and retroperitoneal glandular masses. Dr. Knyvett Gordon rightly remarked that this structure resembled more the type usually described as lymphosarcoma, but that "the essential feature of lymphatic leukæmia is a mixture of lymphoid cells ranging from small lymphocytes through large lymphocytes and lymphoblasts and up to the primitive lymphoidocyte."

The problem is somewhat similar to that of "leukosarcoma" of Sternberg. This author described cases with tumour-like infiltrating growths, especially mediastinal, mostly associated with a leukæmic blood-picture. The cells characterising his cases (just as the cases of Parkes Weber,[4] Scherf,[5] &c.) were of the large type in the blood and also all organs, and the tumour-like masses were permeated by the same type of large lymphocytes. Sternberg considered these cases as distinct from ordinary lymphatic leukæmia, and separated them together with the chloromatosis into a distinct group termed "leukosarcomatosis."

This classification, however, has not been accepted by the majority of hæmatologists. Naegeli,[6] e.g., points out that it is erroneous to consider the large cells, as Sternberg does, as tumour cells, since similar histological pictures are frequently met with in ordinary leukæmias, especially those with an acute course. Pappenheim[2] says that the uniformity of these large cells is due only to the acute precipitated maturation of the cells. He considers also the small-celled lymphosarcomatosis of Kundrat as a variety of "the leukæmic and aleukæmic parenchymatous diseases of the hæmatopoietic tissues" only, and speaking of Sternberg's leukosarcoma he points out that there are not only large, but also small, celled diseases of that type. The generalised benign hyperplastic, as well as the primary malignant diseases of the hæmatopoietic system, are, in his opinion, manifestations of the same pathological process. There is, moreover, only a gradation in the biological "avidity" of the cells, and the malignant type (Pappenheim calls it sarcoid type) shows, in addition to the primary multiple proliferations, also secondary embolic metastases due to an overflow from the rapidly proliferating primary lesions.

Our case showed a general enlargement of glands, and several of them from different parts of the body when examined exhibited the same histological structure. The spleen, liver, kidneys, and bone marrow were found to be infiltrated with the same type of cells. Dr. Knyvett Gordon is further of opinion that the changes in the liver, kidneys, and bone marrow were due to metastases, but this is difficult to prove, and in our view the generalisation of the same type of cell indicates only a primary generalised affection of the hæmatopoietic tissues.

It was very instructive to watch the development of changes in the patient's blood. When we first examined it, the total as well as the relative number of white cells was completely normal. Then a relative lymphocythæmia appeared, with a majority of small lymphocytes. There was also a considerable number of myelocytes present. With the development of the disease the relative number of lymphocytes increased steadily till ten days before the patient's death we got a total count of 60,000 white cells and a differential count of 87½ per cent. lymphocytes, of which the great majority consisted of small lymphocytes. These figures went on increasing up to the patient's death. These changes in the blood could certainly not have been an agonal manifestation, but an inherent symptom of the disease. It is interesting to note that the red cells remained normal and were only slightly affected just before death.

The usual symptoms met with in acute leukæmia—i.e., stomatitis, high temperature, and hæmorrhages—were not of a very marked character. It is interesting to note that Sternberg[7] considers these symptoms as having nothing in common with the leukæmic process itself, but as being due to septicæmia caused by a secondary infection.

Our case gives, in our opinion, a very good illustration of the relationship between lymphosarcoma and lymphadenosis (leukæmic and aleukæmic). Lymphosarcoma, as originally described by Kundrat and Paltauf, is a localised affection of a group of lymphatic glands, never generalised, but infiltrating surrounding tissues and spreading by way of the lymphatics into the neighbouring groups of glands. The penetration into the tissues in the case of a lymphosarcoma is different from that in true sarcoma or cancer. Here the cells never destroy muscles or vessels, but infiltrate the tissues in the same way as in some cases of ordinary leukæmia. For example, vessels are surrounded by the cells, the walls are infiltrated, but the lumen remains free. The infiltrated organs preserve their function and atrophy only late (Rieux).

Spleen and liver are rarely affected. The opinion of authors about the character of blood changes varies; some find a relative lymphocythæmia, others a relative diminution of lymphocytes. The total amount of white cells is in most cases not affected. There are thus usually no marked changes in the blood, and for that reason alone would our case also be quite remarkable. The histological structure of the affected tissues in lymphosarcoma shows an extraordinary proliferation of lymphocytic cells, which are pressed tightly against each other. The cells are uniform in character and mostly of the small lymyphocyte type, but the nuclei have frequently a vesicular aspect and are surrounded by a narrow margin of cytoplasm. There is but little reticular stroma present. There are thus only differences in degree of infiltration between lymphosarcoma and leukæmic and aleukæmic lymphadenosis, while the uniformity of cells makes the position of lymphosarcoma similar to that of Sternberg's leukosarcoma.

A characteristic feature of lymphosarcoma is its limited localisation. But just as myelomas, which are considered by Pappenheim[2] as belonging to the same group of primary diseases of the hæmatopoietic tissue, may be localised or generalised—i.e., associated with a general affection of glands and the spleen (Lubarsch)—so also lymphosarcoma may occur in a localised and a primary generalised form. Hirschfeld[8] mentions such a primary generalised case of lymphosarcoma.

While speaking of the generalised and localised forms we must emphasise that in our opinion even ordinary leukæmia does not commence suddenly as such in a generalised form, but that it is preceded by a shorter or longer period of latency, and probably begins first under the influence of some irritating agent in a group of glands or in the spleen and only gradually becomes generalised.

In Rieux's[1] opinion aleukæmic lymphadenosis and lymphosarcomatosis cannot be separated from each other, because their fundamental basis is the same. He considers the histological differences between them as not of great importance. The essential feature in both is the hyperplastic proliferation of lymphocytes, and there is only a difference in degree of aggressivity between these two clinical forms. In the ordinary form of lymphatic leukæmia the proliferation of cells is often not limited to the glandular structures from which they originate, but they infiltrate the capsule as well as the surrounding tissues. This feature of leukæmia was the reason why Banti[9] regarded it as sarcoma. Ribbert,[10] who looked also upon leukæmia as a generalised neoplasm, did not accept the term sarcoma for it, because he reserved this definition for tumours originating from connective tissue. He thus termed cases with a proliferation of young large cells as lymphoblastoma, while for

tumours characterised by small riper cells he used the term lymphocytoma.

A very interesting point of view is taken by Jolly.[11] He states that those cases of leukæmic and aleukæmic lymphadenosis which show a predominance of a certain type of cell have an aspect similar to the round-celled sarcoma. The difference would lie mostly in the absence of reticular stroma in the case of the latter.

If we take into consideration that many modern hæmatologists like Ferrata,[12] find evidence indicating a relationship between the connective tissue cells and the cells in leukæmic proliferation, this view would not appear unfounded. Fineman[13] points out that in his case of microlymphoidocytic leukæmia he found in the tissues all the morphological stages of metaplasia from a connective tissue cell to his micro-lymphoidocyte. To quote his words: "There are typical elongated connective tissue cells with the clear, pale, almost homogeneous cytoplasmic processus and vesicular pale nuclei. The next cell in the process shows a shortening of these processus. Then, again, a cell may be completely rounded out or oval in shape." If this be so, one would be rather inclined to consider sarcoma and the leukæmic and aleukæmic proliferation as very closely related to each other.

But any attempt at classification must bear here a temporary character as long as the ætiology of both leukæmic diseases and sarcoma remain unknown. We may come with Jolly[11] to the conclusion that "leukæmias represent pathological appearances intermediary between hyperplastic and neoplastic reactions, and their study may thus be able to throw also some light upon the pathogenesis of malignant tumours."

Conclusions.

The points of interest in the case described above are: 1. A benign aleukæmic lymphadenosis with a history of many years takes suddenly the form of a malignant lymphadenosis. 2. The uniform character of cells, corresponding with the histological picture of lymphosarcoma. 3. The generalised character of this malignant process. 4. The change of the aleukæmic blood-picture into a leukæmic one. 5. Evidence of relationship between leukæmia and lymphosarcoma.

FISHERMEN AND ABERDEEN ROYAL INFIRMARY.—Fishermen of Fraserburgh have undertaken to contribute 30*s.* per boat per annum for the next three years in response to the appeal for the proposed new Royal Infirmary at Aberdeen.

ST. BARTHOLOMEW'S HOSPITAL.—Lord Stanmore, the treasurer, reports the excess of total income over expenditure for last year as £9465. Expenditure amounted to £191,648, and the number of in-patients dealt with was 9,802, while 666 out of 688 beds were in constant use. During the year close on 3000 cases of street accidents or illness were brought in by motor ambulances belonging to the Corporation or the London County Council. Lord Stanmore refers to the scheme for the erection of an operation theatre block, a new surgical ward block, and recreation rooms for the nursing staff, at a cost of £200,000.

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS.

THE RESULTS OF RAMMSTEDT'S OPERATION

BY SEYMOUR BARLING, C.M.G., F.R.C.S. ENG.,
HON. SURGEON, BIRMINGHAM CHILDREN'S HOSPITAL.

THE immediate problem to be faced in these cases is how best to tide the infant over the period during which the obstruction of the outlet of the stomach is threatenening life by starvation. As to whether this should be effected by medical measures alone or whether surgical interference is justified is still a matter on which there is considerable diversity of opinion. The question can ultimately be decided on experience and statistical study of the results obtained by either method, but the disease is relatively rare and, furthermore, suitable surgical treatment has only been applied to it during the last few years. Groups of statistics still show great variations in the results achieved by both methods, for these depend more on the environment of the patient than on the disease. for early and prompt diagnosis is the first essential to successful treatment whether by medical or surgical measures. This is well shown in the cases in this series, in which the mortality in the private cases is nil, whilst in "hospital" cases treated by exactly the same methods it is 48 per cent. For statistics to be comparable they must be of cases drawn from the same strata of the population and, if possible, from the same neighbourhood. Early diagnosis and prompt treatment would appear to favour the surgical results to a greater degree than the medical ones in comparable groups of cases, for in selected cases the surgical mortality is probably not more than 5 per cent.; moreover, where the mortalities in the two groups of cases equal, there appear to be some inherent disadvantages in treatment by medical measures alone. Cases so treated demand months of highly skilled nursing, with most meticulous attention to every detail of diet and hygiene, with its attendant anxieties and strain. With surgical treatment the time required is much shorter, and in the course of two or three weeks, as a rule, the child is fit to return to its mother in an ordinary home—in not a few cases in this series the infant has returned home before the tenth day. The degree of obstruction undoubtedly varies in different cases, and there is no method of diagnosing this accurately early in the course of a case; were it possible to do this it might be feasible to suggest medical treatment alone for the slighter cases and reserve operation for the higher degrees of obstruction. To try medical treatment at first and then change to operation at a later stage, when the child has gone further downhill, is to court disaster in the average case. As far as can be ascertained, cases that have recovered, whether treated medically or surgically, grow into healthy children free from digestive troubles, but such study of cases has not been sufficiently prolonged to be certain of the end-results. Undoubted cases are on record in which adults have been found suffering from obstruction due to hypertrophy of the circular fibres of the pyloric musculature; such cases may be lesser degrees of the infantile condition which have survived to adult life. It is not unreasonable to suppose that cases cured by medical means alone may add to the number of such adult cases. Operation by division of the muscle and herniation of the mucosa would appear likely to avoid the risk of incompetence of the pyloric canal developing later.

The cases in this series, 90 in number, were, almost without exception, all admitted under the care of my colleague Dr. Leonard Parsons, and he has been responsible for the diagnosis and the pre- and post-operative treatment. With one exception, all of the cases have been operated on in the Birmingham Children's Hospital, the private patients being admitted into the paying wards of the hospital.

rom the time the series starts in 1919 it has been is rule to have treated by operation all cases of ıe disease admitted under him, and many of the ıtients were extremely wasted and ill, and very ɔor operative risks, even for this disease. Two ıses died during the short period of preparation apsing between admission and operation. Diagnosis as made on clinical findings, supplemented in a ɔrtain number of cases by the X ray examination. he latter is not now used as a routine, though for period it was used regularly. It is somewhat ɔsetting to the infant and is not necessary to tablish the diagnosis. In two cases the diagnosis as at fault; in one, early in the series, the child ıd pylorospasm only and recovered, in the second ıse the child had a pyloric stenosis without hyper-ophy, and accompanying this was a stenosis of the ıodenum—it died. As a rule, before operation the fant has a few days' treatment in hospital, with ctal and stomach lavage daily, and immediately ɔfore going to the theatre a subcutaneous saline is ven.

The Anæsthetic.

In the majority of the cases nitrous oxide and ɔxygen has been used, and it is now the anæsthetic choice. It is less toxic than a mixture of ether and ıloroform used in the early cases. The latter was equently followed by hyperpyrexia, whereas with trous oxide, though a temperature of 100° F. is casionally seen, as a rule no reaction occurs, and the ıild quickly recovers. Its administration requires eat skill, and I have to thank Dr. Harry Feather-one for his assistance with these cases. Relaxation the abdominal wall is good as a rule, though casionally a little ether may be necessary to supple-ent the nitrous oxide to attain this. In the series 90 cases, 36 died, a mortality of 40 per cent.

Mortality in Private and Hospital Cases Compared.

As has been frequently noted by all observers, the ortality of the private cases is considerably less an that of those from the hospital class. The lative proportions of these two types of case is a ɔint which must be borne in mind when judging ıtistical results. In the present series there were private cases, and all of these made good recoveries. we deduct these cases, the mortality amongst the hospital cases was 48 per cent.

Several explanations have been offered as to the use of the strikingly different mortalities of the ɔspital and private cases. That it is not due to the ıfavourable results of treatment in an institution opposed to treatment under home conditions, is own by the present series, in which private and ɔspital cases were (with one exception) all treated the same institution though in different wards. every way the nursing and medical care of the two oups was comparable, except that, as a rule, the ımber of patients at a given time would be greater the public than the private wards, and it is possible at this may have played some part in bringing ɔut the striking difference between the two groups, ɔking to the susceptibility of these children to teric infections in the post-operative period. Such fections are known to spread if the number of fants in a unit is proportionally high. A more ɛely explanation of the difference between the two oups is the relatively earlier diagnosis in the private ses, and this, as has already been stated, is the y to successful surgical treatment. Thus in a oup of private cases the average time which mptoms had existed before operation was 13 days, a comparable group of hospital cases it was days for cured cases and 25 days for cases that ed. The importance of these figures becomes anifest when we realise that these infants often se 1 per cent. of their body-weight each day that eatment is delayed.

Rammstedt's Operation: Its Results.

Rammstedt's operation is simple and efficient, it n be carried out speedily, and causes little operative trauma. Briefly, it consists of a longitudinal incision into the thickened pylorus. By this the thickened circular muscle-fibres are divided right down to the mucosa, thus allowing the mucosa which is tightly infolded in the grip of the muscle to expand and fill the gap in the incised muscle. By this means the pyloric canal becomes competent to allow the stomach contents to pass. The risks of the operation are: (1) operative shock; (2) hæmorrhage; (3) perforation of the mucosa of stomach or duodenum; and (4) inadequate freeing of the mucosa.

Of the 36 cases which were fatal, 14 died within 24 hours of operation, and in four of these cases bleeding from the divided muscle was the cause of death, and in the other ten patients no cause could be found other than inanition and the shock of operation. These cases were all desperately bad beforehand and unable to survive even the slight trauma inflicted. Looking over the histories of the ten cases, it may be fairly said that they were too late to survive with any form of treatment, as it is a striking fact that in this group the average time during which symptoms had existed was no less than 50 days, which is double that of the average fatal case, and three times that of the cases which recovered. Every precaution must be taken to eliminate shock by speed in operating —suitable anæsthesia, warmth before, during, and after operation, and by subcutaneous and rectal salines before operation and after returning from the theatre. Even with such precautions such late cases will have a heavy mortality, though occasionally one recovers even when every factor is against this in late diagnosis and severe inanition. Thus one case in which symptoms had been present for 45 days and the patient had lost 25 per cent. of the birth weight (7½ lb.) made a good recovery and left hospital in under three weeks.

In the majority of the cases the hypertrophied pylorus is relatively avascular, and oozing from the divided margins is not troublesome; in occasional cases there is troublesome oozing or bleeding from a minute vessel in the subserous coat. The loss of four cases in this series from hæmorrhage indicates the danger from this source, a danger which was insufficiently realised in the earlier cases. The tissues are so fragile that it is almost impossible to deal with the bleeding-point by ligation, though this may sometimes be possible. Further danger is to be feared from hæmorrhage occurring from the margins of the incision during the period of reaction following the operation, though hæmostasis may appear to be perfect when the abdomen is closed.

With nitrous oxide anæsthesia the necessity for speed in operating is not so great as formerly and more time can be spent in attention to the detail of hæmostasis. A fragment of the rectus muscle taken from the margin of the wound, and applied by steady pressure for one minute to the bleeding area, has been the most successful hæmostatic in my hands. One of the more obvious risks of the procedure is perforation of the gastric or duodenal mucosa in the depths of the incision. This can be obviated by care in dividing the muscle and by the recognition of the sudden thinning of the hypertrophied muscle at the duodenal end of the canal. There were no deaths from this cause in the present series.

When the operation is completed the incision must gape widely and the mucosa be freely herniated through the gap; the muscle itself is very loosely attached to the underlying mucosa and is very brittle and easily divided by a blunt instrument; it is easy, however, to overlook a few circular strands of very tough fibres lying next to the mucosa. If left undivided these restrict herniation and may be responsible for allowing scar formation to close up the canal if the child survives a few weeks. In such cases the child makes a bad recovery or dies some weeks after operation with symptoms of stenosis, manifest by vomiting, reappearing a fortnight or so after operation.

Cases which survive the immediate risks of operation still require the greatest care in the post-operative

period. As a rule, the length of this period bears a direct relationship to the length of time the symptoms have existed before operation. The chronic gastritis and hugely dilated stomach resolve but slowly; whilst the atrophic intestine is ill-adapted to resume function at once. Many deaths occur in this post-operative period from the third to as late as the fiftieth day. If breast milk is available the risks of this period are definitely lessened by its use. All forms of artificial feeding appear to be attended with increased risk, though the use of lactic acid milk appears to be attended with less danger than other substitutes. Not a few of the cases have a terminal diarrhœa with green stools. In others steady loss of weight occurs and the child gradually fades out. A too rapid increase of diet, although it is attended by a satisfactory rise in the weight at first, carries with it the risk of an enteritis from non-absorption caused by the great atrophy of the small intestine which is present. This atrophy takes two or three weeks to adjust itself to the new conditions resulting from the opening of the pylorus. Cases that run a favourable post-operative course often gain no weight for the first fortnight, a slight loss in the three days following operation is followed by a period during which the weight is maintained, and then the weight begins to increase very slowly—at the end of a fortnight the weight at the time of operation is reached—onwards from that time the rate of increase may be allowed to accelerate more rapidly. As a general rule, cases which come to operation within a week or two of the onset of symptoms have a quiet convalescence, whereas cases in which the operation is late cause constant anxiety owing to the gastritis and intestinal atrophy which is present, and not a few of these die some weeks after operation from these causes.

Conclusions.

1. All cases admitted to one hospital unit during the years 1919-26 were submitted to Rammstedt's operation. The mortality in 90 cases was 40 per cent. 2. Included in the series were 15 private cases. None of these died. 3. The great difference in mortality-rates in the "hospital" and "private" cases is mainly due to earlier diagnosis in the latter cases. 4. If all cases of the disease could be operated on within 14 days of the onset of symptoms, the mortality would probably not be more than 5 per cent.

AN OUTBREAK OF ILLNESS CAUSED BY *B. DYSENTERIÆ* FLEXNER.

BY S. H. WARREN, M.R.C.S. ENG., D.P.H. LOND.

(*From the Bacteriological Laboratory, College of Medicine, Newcastle-upon-Tyne.*)

THE following outbreak, at first regarded as food poisoning, proved to be due to infection with *B. dysenteriæ* Flexner and, unlike the sudden explosion of illness usually met with in food poisoning, consisted of a series of cases separated by intervals of a few days. A very careful inquiry into the sources of the foodstuffs ingested was made by the health authorities at the time, and no evidence tending to incriminate any particular item could be obtained, although a sample of tomatoes, which fell to some degree under suspicion, was sent to the laboratory for examination and a proteus-like organism was isolated therefrom.

History of the Outbreak.

The illness was entirely confined to two families who lived together in a two-roomed flat, sharing the same scullery and w.c., but cooking and eating separately. The larger family (M.) consisted of father, mother, and three young children, of whom the three children alone were affected, and of these two died. The second family (B.) consisted of an aged man and an adult daughter; the former suffered from diarrhœa and was found to be passing the same dysentery bacillus while the latter showed no evidence of infection.

The first case, J. J. M., aged 6, was taken ill on July 2nd with abdominal pains, desire to defæcate, and vomiting followed later by diarrhœa with foul-smelling, greenish yellow stools. He died on the 4th, having been seen by a doctor for the first time a few minutes previously. No bacteriological examination was carried out in this instance.

The second case, T. W. M., aged 2, was taken ill on the afternoon on July 5th, the day following his brother's death with a sudden attack of abdominal pain, followed by diarrhœa and just before death, which occurred next day, by vomiting. A post-mortem examination, held on the 6th, showed redness and inflammation of the mucous membrane of the large intestine throughout its entire length, its contents consisting of mucus and thin yellow fluid. Slight injection of the stomach and the lower end of the ileum, with enlargement of Peyer's patches and the solitary follicles, was also noted. This child was said to have suffered from diarrhœa 18 months previously. The brain, spleen, liver, stomach, and intestine were received at the laboratory on the 7th, and the strain of *B. dysenteriæ* Flexner to be described was isolated from all of these organs.

The third case, R. M., aged 5, the remaining brother was taken ill on the evening of July 9th, or four days after the onset of illness in the second case. He suffered from diarrhœa and the mother stated that there was blood and mucus in the stools, an observation later confirmed in hospital. He appears to have suffered a comparatively mild attack and subsequently recovered. This boy's fæces were examined as were also those of the rest of the family on the 8th, the day before his attack began, and the dysentery bacillus was isolated, but other specimens four and 18 days later were negative. His blood, when tested on the 19th, agglutinated both his own organisms and also the X strain of *B. flexner* up to 1 in 250, and the Z strain of *B. flexner* to 1 in 12½.

The fourth case, Mr. B., aged 70, suffered merely from an attack of diarrhœa on July 11th (two days after Case 3) and his fæces, examined next day, yielded the same organism although negative later on the 28th. He was treated by a doctor, being put to bed, and recovered. His blood agglutinated on the 22nd 1 in 125 to the X and Z strains of *B. dysenteriæ* Flexner, and also the organism recovered on the 13th. His fæces when examined seven months after the outbreak were free from dysentery bacilli.

Members of the two families who showed no signs of infection.—The fæces of Mrs. M., aged 32, the mother of the family, were examined on July 8th with negative result, but when the examination was repeated 20 days later the same strain of *B. dysenteriæ* was once more isolated. Her blood also agglutinated the X and Z strains of *B. dysenteriæ* Flexner to 1 in 25 on the 19th. The fæces examined seven months after the outbreak were free from dysentery bacilli. Examination of the fæces of Mr. M., the father, proved negative on two occasions, but his blood on the 19th agglutinated *B. flexner* X to 1 in 50 and Z to 1 in 12½. Lastly, the remaining member of the two families, A. B., aged 25, gave entirely negative results in two examinations of her stools and her blood was not examined.

Summary.

It will be seen, therefore, that of seven people involved in these two families, four were infected with a Flexner dysentery bacillus. In one case the organism was recovered post mortem, and from the other three from the stools during life. Further, the bloods of all four agglutinated the organism recovered as well as standard strains of *B. dysenteriæ* Flexner. In all except the two fatal cases the bloods were examined for the presence of agglutinins of *B. enteritidis* Gaertner, *B. aertrycke* (Mutton and Nenport), but always with negative results.

The bacillus isolated from all these sources invariably gave the reactions and showed the general characters of *B. dysenteriæ* Flexner. When tested against the Oxford Flexner type sera they gave the uniform similar results recorded in the following table:—

Strain ..	1 in 25	1 in 50	1 in 125	1 in 250	1 in 500	Cont.
Serum V ..	+	±	−	−	−	−
,, W ..	−	−	−	−	−	−
,, X ..	+	+	+	+	±	−
,, Y ..	+	±	−	−	−	−
,, Z ..	+	+	+	+	±	−

Repeated absorption experiments were subsequently carried out with anti-sera prepared in this laboratory from the organism isolated and from different strains

B. dysenteriæ Flexner types X and Z, and also th sera obtained elsewhere, but no clear-cut results re ever obtained, and the results all pointed to a nsiderable admixture of both types in the structure the organism isolated.

Discussion.

Although this outbreak cannot be regarded as " food isoning " in the strict sense of the term, or comrable to the instances of the sort quoted by Savage d Bruce White as due to the dysentery group of ganisms, food cannot be precluded as a possible nicle of infection. It was not possible actually determine the primary source of infection, but, Nabarro suggests, the dysentery infections may much more frequent in this country than is mmonly supposed. We have actually isolated veral strains of Flexner dysentery bacilli from the ols of children suffering from diarrhœa as patients the Children's Hospital here.

In this instance no definite history of dysentery uld be obtained. One child (Case 2) is said to have fered from diarrhœa 18 months previously, the ise of which is unknown. Mr. M. had not served the army or been abroad. Mr. B. had been a lor but only on local fishing boats and had not ited foreign ports. Mrs. M. was at least a temary carrier as the organism was isolated from stools on one occasion, about 14 days after the ies started, but she appeared to remain well. doubt in the confined condition under which these nilies lived there was ample opportunity, using same scullery and w.c., assisted probably by flies, both families to become infected.

As regards the finding of the dysentery bacillus all the tissues of Case 2, it is the universally accepted perience that dysentery bacilli hardly ever invade blood stream and can rarely be isolated from the id organs post mortem. The writer was not present the autopsy, but the organs were sent to the oratory later in separate vessels. The usual liminaries of sealing, &c., were carefully carried .

The outbreak showed this dysentery bacillus to be cially virulent for children and the aged, and it s actually fatal to two children after a very short ess. Full grown adults appeared not to be affected. ally, the diagnosis as to the cause of the outbreak s only possible as a result of fairly extensive teriological investigation.

wish to express my indebtedness and thanks to . H. Kerr, medical officer of health, Newcastle-upon-ne, for the clinical history and the specimens for mination in this investigation.

OBSERVATIONS ON THE SCHULTZ-CHARLTON REACTION.

BY J. C. BLAKE, M.B., B.S. LOND.,
SECOND ASSISTANT MEDICAL OFFICER, NORTH-EASTERN HOSPITAL, METROPOLITAN ASYLUMS BOARD.

N carrying out these investigations with scarlet er antitoxic sera it has been assumed that the ultz-Charlton reaction provides a reliable indication to the therapeutic value of the serum. But before ling with this aspect there are some points with ard to the test which may be of interest.

First, as to the amount of the injection; it has n the custom to inject 0·2 c.cm., but it was thought sible that better results might be obtained if a ger quantity were used, especially in reducing the centage of cases of scarlet fever which fail to give Schultz-Charlton reaction. With this object in w a number of patients were given two injections a serum (or two sera), the first injection being c.cm., the second 0·5 or 1·0 c.cm. In each instance reactions were all positive or all negative. In se cases which gave positive results the areas of blanching caused by the larger injection were increased, but not proportionately to the difference in the amount. In other words, increasing the quantity of serum does not increase the probability of blanching, and though it causes no more inconvenience to the patient there does not appear to be any advantage in it.

Secondly, with reference to the strength of serum; when the test is being used for diagnostic purposes, undiluted or a 1 in 10 serum gives the best results. It is more common to find patches of erythema in the blanched areas than with higher dilutions, but this erythema fades in the majority of cases within 24 hours. A larger percentage of positive reactions is obtained than with higher dilutions and blanching usually appears earlier by several hours.

The action of scarlet fever antitoxic serum injected intradermally was demonstrated in the following manner.

A patient, injected on the first day of the rash, showed large areas of complete blanching (2 in. by 1½ in.). Three days after the test—i.e., on the fourth day of the rash (and fifth day of disease), Dick toxin and control were injected intradermally in two blanched areas. In addition, Dick toxin and control were also injected where the rash was still prominent. Twenty-four hours later the Dick toxin injected into the rash produced an area of intense erythema (1 in. by ½ in.), showing distinctly through the rash, and which lasted for three days. No such reaction occurred in the blanched areas. This test was repeated on another patient with similar result. Thus the serum injected was more than sufficient to neutralise the toxin causing the rash, if this is the explanation of the reaction. In this connexion absence of desquamation in the blanched areas, when the latter persist until the rash fades, has been observed in a number of cases.

In estimating the therapeutic value of scarlet fever antitoxic sera by means of the Schultz-Charlton reaction, the degree or intensity of blanching and the dilution of the serum must be taken into consideration. In many cases the blanching is never complete, the rash being only partially obliterated, and this type is usually evanescent. In another group of cases the blanching is complete but is gradually encroached on by the rash and eventually disappears. In a third group the blanching is complete and the area and intensity remain undiminished until the rash fades. I take this to mean that in the first group the antitoxin is insufficient to neutralise the toxin causing the rash; in the second that it is only just sufficient, and in the third that it not only neutralises the toxin present at the time, but also any subsequently invading the area from the blood stream or injected intradermally.

With regard to dilution, two sera may give practically the same results until high dilutions are employed when the difference in potency becomes apparent.

By making these observations sera from different strains have been compared and the advantage of using concentrated sera has been shown. In one series of cases concentrated serum gave good results when diluted 1 in 16,000, but no blanching could be obtained with the unconcentrated beyond 1 in 8000. The central erythema, already referred to, was found to occur with about equal frequency with concentrated and unconcentrated sera, which would suggest that it is not a protein reaction. True serum rashes do occur in the form of urticarial weals confined to the blanched area three to four days after the injection.

These observations were made in a series of 132 cases, in 97 (72·5 per cent.) of which there was blanching. In my previous series [1] of 168 cases, 72·6 per cent. reacted. Thus there are some 37 per cent. of cases of undoubted scarlet fever which failed to blanch with specific sera. But in considering these figures it must be pointed out that in a number of

[1] Metropolitan Asylums Board Annual Report, 1925–26, p. 171.

cases only high dilutions were used. If only those cases are taken which were injected with undiluted or 1 in 10 serum, the percentage of negatives falls to 22 per cent. Another factor to be borne in mind is the " age " of the rash. A rash that has been present three days is less likely to react than on its first appearance. The actual figures in this series are as follows :—

1st day rashes ..	..	83·3 per cent. positive.
2nd ,, ,, ..	..	75·0 ,, ,,
3rd ,, ,, ..	..	50·0 ,, ,,

All cases tested on the fourth day were negative, and it seems probable that the reaction can very rarely be obtained on or after the fourth day. The average interval before blanching occurred was 14½ hours, the shortest time being 6½ hours. In two cases blanching did not occur until at least 36 hours after the injection. Normal horse serum was used as a control in amounts varying from 0·2 to 1·0 c.cm. in 17 cases, and no blanching occurred.

Non-Specific Sera.

In February last, at the suggestion of Dr. R. A. O'Brien, we started using non-specific sera for the Schultz-Charlton reaction. The sera used were prepared from the streptococci of erysipelas, puerperal fever, cellulitis, and from a case of streptococcal toxæmia. The results were surprising. The following table gives some of the results. In each case the various sera used were injected at the same time.

Case No.	Sc. fever antitoxic serum. Dil. 1 in 10.	Puerperal serum.	"Cellulitis" serum.	"Erysipelas" serum.	"Streptococcal" toxæmia serum.	Multivalent antistrept. serum.
5	Pos.	Neg.	Neg.	Pos.	—	—

28	Pos.	Pos.	Pos.	Pos.	—	—

V. sl. reac. = Very slight reaction. * 1 in 10.

A scarlet fever serum, known to give good results, was used in each case as a control, and in no instance up to the present has this control failed to blanch when reactions have been obtained with non-specific sera. On the contrary the scarlet fever serum has in most cases produced larger areas. From the table above it will be observed that multivalent antistreptococcal serum was used. This naturally suggested itself when reactions had been obtained with several of the non-specific sera. The areas it produced were much larger than those of the control (sc. fever) serum when used undiluted, but when it was diluted 1 in 10 the areas were slightly smaller than those of the control.

This multivalent serum was prepared from numerous strains of streptococci which included two strains of scarlet fever streptococcus, and was taken from horses which had previously been immunised against scarlet fever toxin. If at some future date we find a number of cases reacting to a serum non-specific to scarlet fever, and not to scarlatinal antitoxic serum, further investigation of these cases may provide valuable information on the ætiology of scarlet fever.

ROYAL NORTHERN HOSPITALS.—The total income for maintenance of the Royal Northern group of Hospitals last year amounted to £81,454, as against £85,859 the year before. The total maintenance expenditure increased from £86,596 to £89,232, but this was partly due to the increased number of patients and partly to an additional 21,852 out-patients' attendances. An indication of the progress of the hospital is seen in the increase in the total income of the hospital, which in 1913 was only £24,608.

Clinical and Laboratory Notes

A CASE OF MULTIPLE DIVERTICULA OF THE JEJUNUM.

BY J. ALLAN BERRY, M.S. DURH., F.R.C.S. EDIN.,
MEDICAL SUPERINTENDENT, NAPIER HOSPITAL, NEW ZEALAND.

VERY few examples of diverticula of the jejunu have been placed on record. James T. Case,[1] writin on diverticula of the small intestine other tha Meckel's diverticulum, collected only 17 cases recorde between 1854 and 1920. Helvestine,[2] writing two yea later, refers to 27 cases of false diverticula of t jejunum. In view of their apparent rarity in t small intestine the following record appears to worthy of publication.

A man, aged 70, was admitted to hospital in Augu 1920, suffering from the effects of prostatic obstructio and died from uræmia. A history was obtained, in additi to his urinary symptoms, of some digestive trouble whi was described as flatulence, and multiple diverticula of t small intestine were discovered at autopsy. The sm intestine—with the exception of the duodenum, which w free from diverticula—was removed and measured 6·3 metr in length. There were upwards of 50 diverticula, and th were limited to the first 2 metres of the intestine, the r of which showed no abnormality. They were divisible in two groups, large and small, and there were very few intermediate size. Small diverticula occurred throughc the whole length, but the large ones were limited to distance of less than the first metre, except for a solita large one which occurred, as a last example of the conditic 2 metres from the duodeno-jejunal flexure.

The first diverticulum arose from the mesenteric atta ment about 25 cm. from the duodeno-jejunal flexure, a then projected forwards on the right side of the gut, to whi it was bound by rather dense whitish adhesions. Th could easily be freed, when it was found that the diverticul was spheroidal in shape and communicated with the intesti by a narrow opening bounded at its margins by longitudin muscle-fibres. The sac itself was thin-walled, covered serosa, and measured 2·5 cm. in length and 1·5 cm. at widest part. About 5 cm. further down was a similar l larger diverticulum about 3·75 cm. in length and abc 2·5 cm. at its widest part. Another 9 cm. further on w a diverticulum of about the same size, but this ti attached to the left side of the intestine. Then followe large number of small diverticula which measured on average about 1 cm. in all directions. These projec directly backwards into the mesentery. Up to a distance less than 1 metre from the duodeno-jejunal flexure an there were about half a dozen large diverticula, usua attached to the intestine on the right side. For the remain of the distance they were all small except for the la diverticulum which terminated the series and was simi to those described in the upper part of the intestine.

At a distance of about 1·25 metres from the l diverticulum were two lipomata, each about 5 cm. diameter, arising in and situated on either side of mesentery, nearly opposite one another. They did contain diverticula. On opening the intestine the stom leading into the diverticula, large or small, were all abc 1 cm. in diameter. Those diverticula that were oper were found to be empty. There was no evidence diverticula of other organs beyond a small inflan diverticulum of the sigmoid colon.

Discussion.

Case[1] in 1920 made the first diagnosis of t condition by means of radiological examinatio E. L. Hunt and P. H. Cook,[3] writing in 1921, regard these diverticula as relatively common, an opini which is probably correct, and described them roughly pear-shaped, measuring about 3 cm. depth and 3 cm. in width. The openings into t intestine were about 1 cm. in diameter. All t diverticula went directly backwards into the mesente

[1] Jour. Amer. Med. Assoc., 1920, lxxv., 1463.
[2] Helvestine: Surg., Gynæcol., and Obstet., 1923, xxxv 1–5.
[3] Ann. Surgery, 1921, lxxiv., 746.

L. Braithwaite [4] described and figured a beautiful imen of multiple diverticula of the jejunum for h enterectomy was necessary. The diagnosis had n made by Dr. L. A. Rowden after radiological nination. The diverticula extend directly back- ls into the mesentery. Helvestine [2] described cases, the first of which is strikingly similar to one I have recorded.

ne patient, aged 70, suffered from the effects of an ged prostate which resulted in uræmia and death. diverticula were 58 in number, the largest in size being e nearest the duodenum. They were spheroidal in e, and the stomata which connected the diverticula the intestinal lumen were much smaller than the y of the diverticulum. This point is well illustrated in ure which displays the intestine laid open from the nesenteric border and shows the stomata leading into diverticula.

r Berkeley Moynihan,[5] in discussing these diver- la, remarks: "The pouches may be numerous, rarely larger than a walnut, are usually on the enteric side, and because of their large orifice do as a rule, retain food for long periods and do not, efore, often lead to serious complications." The ement that the diverticula have a large orifice, and this is the explanation for their not often leading rious complications, is not borne out by the present , nor by a number of other recorded cases in which point is mentioned. Where the diverticula are ll the orifice appears to be as large as the cavity, as soon as the diverticulum approaches its usual imal dimension—of something less in size than a ut—the orifice is actually much smaller than the ty. Typically it appears to be seldom more than n. in diameter, although in cases of perhaps long ding it is sometimes larger.

n interesting point in the present case is the fact all the larger diverticula turned forwards and rally to the right side, obtaining secondarily an chment by means of adhesions to the intestine f. This does not appear to have been noted in r cases. It would seem that in the early stage of nation of the diverticulum the line of least tance is directly backwards between the leaves of mesentery, but as the diverticula become larger generally tend to project much more on the right of the mesentery than on the left, and in some nces are actually turned forwards. Their pro- on, as a rule, on to the right side, may possibly be ained by the oblique attachment of the mesenteric , and the fact that resistance on the left side he mesentery may be greater than on the t side, owing to the disposition of the coils of stine.

arious theories have been advanced to explain the ation of these diverticula, and there can be no ot that they do not all have the same origin. vestine[2] mentions three factors: (1) traction by mesenteric vessels or traction following adhesions; legeneration of the musculature; and (3) increased a-abdominal pressure-tension, leading to increased a-intestinal tension, in the causation of which al and vesical tenesmus play an important part. static retention, as in Helvestine's first case, also in the present case, must be regarded as a very nt factor in the formation of acquired or false rticula of the jejunum.

the diverticula are entered by the fluid contents ne jejunum they cannot empty themselves by any ractile power of their own, for they possess in most nces very little musculature, and it is likely that tying is brought about by the pressure of the ounding coils of intestine in active contraction. t fluid contents do enter the diverticula is proved radiological examination, and the emptying is a process.

y thanks are due to Dr. H. Nockolds for permission ecord this case.

A CASE OF MENINGITIS DUE TO A HÆMOPHILIC BACILLUS.

BY JOHN A. BRAXTON HICKS, M.D., M.R.C.P. LOND., D.P.H.,

DIRECTOR OF THE JOHN BURFORD CARLILL LABORATORIES, WESTMINSTER HOSPITAL.

THE article by Dr. John F. Taylor in THE LANCET of June 25th (p. 1341) on Suppurative Arthritis Due to Hæmophilic Bacteria prompts me to publish a brief account of a recent case of suppurative meningitis due to similar organisms.

A female, aged 1 year and 3 months, in the children's ward of the hospital under the care of Dr. Donald Paterson, came to the post-mortem table 19 days after admission. Permission to examine the head only was given by the relatives. On examination, pallor and well-marked carpo-pedal spasm were present. The skull bones were greatly engorged, particularly the inner table, and the dura mater fairly firmly adherent to the brain tissue beneath. This adhesion had been caused by the presence of a thick layer of deep yellow-green pus which was plastered over the entire vertex and base of the brain. The pus was plastered on so thickly that in many places the normal contour of the sulci and convolutions was obliterated. The greenish-yellow colour of the pus mingling with the bright red colour produced by the vascular engorgement gave to the brain, when viewed *in situ*, a most striking marbled appearance. Pus was present in both the ventricles of the brain, but not to any marked degree. Middle ears and other sinuses that could be examined from within the skull showed nothing abnormal. The meningeal pus contained minute "influenza-like" bacilli.

Three samples of cerebro-spinal fluid sent to the laboratory for examination on the third, fifth, and seventeenth days after admission were all more or less similar in character, save that the last was very much more purulent than the other samples. The leucocytes of the first sample numbered 208 per c.mm., about 40 per cent. of them being polymorphonuclears, and there was only a light purulent coagulum. The last sample contained a large purulent deposit (leucocytes not enumerated) of an entirely polymorphonuclear type. All samples contained large numbers of a minute pleomorphic, Gram-negative bacillus. Visible growth was only obtained on blood-agar (4 per cent. of whole blood), and then only after 48 hours. The growth was fairly copious, and consisted of minute transparent colonies, like small watery streptococcal colonies, and these were non-hæmolytic. Morphologically, the bacilli were more pleomorphic in culture than in the direct films from the cerebro-spinal fluid. In the films the bacilli appeared as minute rods of varying length, and also as cocco-bacillary forms. In the cultures, in addition to these shapes and sizes, one encountered filamentous forms. In some respects, therefore, morphologically, the bacillus resembles the *Bacillus influenzæ*, but the tendency to filament formation is more marked.

With the greatest difficulty one set of subcultures was obtained on blood-agar, and an emulsion from one of these tubes was made. The emulsion was not actually counted, but it was approximately 1000 millions per c.cm. by opacity; 1 c.cm. of this emulsion (approximately 1000 million living organisms) was injected into the peritoneal cavity of a guinea-pig of 500 g. The guinea-pig lived 28 hours and died quite suddenly, having exhibited very few symptoms of illness and eating well till the last. The peritoneal cavity of the guinea-pig was much injected, and the visceral and parietal peritoneum fairly thickly coated with a layer of yellow-green pus, very similar to that seen on the meninges of the patient. The rest of the viscera showed the usual pallor associated with a toxæmia, particularly the kidneys. The bacilli were found in the pus, but all attempts to grow them from pus or heart-blood failed.

This difficulty of keeping the organism alive in subculture or after passage through animals is in striking contrast to the behaviour of *B. influenzæ*. The organism undoubtedly is similar to those so admirably described in a paper on Meningitis Due to Hæmophilic Organisms by H. Henry,[1] to which the reader is referred for excellent microphotographs and bibliography. It would appear to be in the same class as the organism Type "Brook" he mentions.

[1] Jour. of Path and Bact., 1913, xvii., 174.

This one failed to give a blood infection in animal experiments.

With other authors, I feel bound to express a grave doubt as to these hæmophilic bacilli of meningitis or arthritis being true *B. influenzæ*. During the war, I was concerned at the Royal Herbert Hospital with investigating an enormous amount of pathological material in the pandemic of 1918–19.[2] With regard to *B. influenzæ*, the following facts stand out (1) It is readily cultivated on suitable media; (2) it grows readily in subculture and does not die out if subcultured at intervals of 4–6 days; (3) it is practically innocuous to animals. In view of my experiences of the 1918 epidemic, one other thing interests me particularly, and that is that the hæmophilic organism I now describe produces in human beings a most intense meningitis, from which the organism can be readily recognised in the cerebro-spinal fluid and pus. Now in the pandemic of 1918 the laboratory at the Royal Herbert Hospital did not receive one spinal fluid or perform one autopsy on a case of suppurative meningitis, although the case-incidence of influenza was well over 2000. A case may have been missed, but certainly meningitis must have been extraordinarily rare.

Thus on cultural grounds from animal experiments, from clinical and epidemiological evidence, I consider that the hæmophilic group of bacilli responsible for the rare cases of meningitis and arthritis, or both, which have been recorded by various authors from time to time, must be kept entirely separate from the *B. influenzæ* of Pfeiffer, with which it has only a morphological resemblance and no true relationship.

A NOTE ON
FEMORAL HERNIA IN CHILDREN.

BY ROBERT RUTHERFORD, M.R.C.S. ENG.,
HOUSE SURGEON, BELGRAVE HOSPITAL FOR CHILDREN, LONDON.

THE following case came under observation at the Belgrave Hospital:—

A girl, aged 4 years and 2 months, was brought to the out-patient department on account of a swelling the size of a walnut in the right groin. It was just external to the pubic spine, and below Poupart's ligament; there was an impulse on coughing, and the swelling was reducible.

At operation a vertical incision was made over the swelling and the diagnosis of femoral hernia was confirmed. The sac was opened and found to contain omentum only; this was returned into the abdomen and a radical cure was performed.

Since the condition is rare in children, it may be of interest to submit the following statistics from the records of the Belgrave Hospital during the period 1908–27. The total number of herniæ that came to operation was 1098, of which 946 (86 per cent.) were inguinal, 148 (13 per cent.) were umbilical, and 5 or 0·4 per cent. were femoral. Of these five femoral herniæ, four occurred in females. The ages ranged from 4 to 7 years. (The age-limit for admission to the Belgrave Hospital is 10 years for boys and 12 years for girls.) Four were right-sided and one was left-sided. A parallel percentage is published by Prof. José Ribera y Sans, of the Hopital l'Enfant Jesus at Madrid, who [3] states that of 3098 herniæ 14 (0·4 per cent.) were femoral.

I am indebted to Mr. C. P. G. Wakeley for permission to publish this case.

METROPOLITAN HOSPITAL.—The total income of the Metropolitan Hospital, Kingsland-road, last year was £30,338 and the total expenditure £30,332. A new nurses' home, of which the Queen recently laid the foundation stone, is being erected at a cost of over £60,000, and will accommodate 60 nurses and six sisters.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Continued from p. 394.*)

SECTION OF DISEASES OF CHILDREN.

WEDNESDAY, JULY 20TH.

THIS Section met under the presidency of Pr JOHN FRASER (Edinburgh), and the subject of d cussion on the first day was

ACUTE PNEUMONIA IN EARLY CHILDHOOD.

Dr. CHARLES MCNEIL (Edinburgh) said that the purpose of the discussion he would use a series 558 cases of acute pneumonia admitted to his wa during the last six and a half years. Slightly m than half the patients were under 2 years old and these the mortality was 30 per cent., whereas in childr from 2 to 12 years the mortality was 5·7 per cent. i.e., the disease was far more common and m deadly during the first two years of life than in t succeeding years of childhood. Such facts suggest the question—What is the prevailing type in t fatal cases, lobar pneumonia or broncho-pneumoni Dr. Agnes Macgregor had investigated this point 100 fatal cases and had found that lobar pneumon as compared with broncho-pneumonia was a r disease. As a pathological process lobar pneumo was the simpler type; as a result of inflammatio fibrinous exudate was poured out into the alve but at this stage and later the framework of the lu including the bronchial walls, seemed to be undamag At the crisis a rapid resolution of the alveolar exud took place. Alveolar pneumonia was a more accur description of the pathological process than lob pneumonia, and explained better its clinical cou Broncho-pneumonia, on the other hand, was a m complicated process and showed much variation the extent and importance of the morbid changes. addition to the varying type of exudate in the alve and bronchi the interstitial framework of the lu showed inflammatory changes. Interstitial pneumo was a better term than broncho-pneumonia, for was the interstitial inflammation which determi the longer course of the disease, its greater immedi danger of extensive and fatal spread, and its grea risk of permanent damage to the lung tissues fibrosis, bronchitis, and bronchiectasis. Many poi were described by which the two types of pneumo might be distinguished during life, but Dr. McN suggested that the cardinal differential signs were o two: the duration of fever and the rapidity resolution. There was long fever and slow resolut in broncho-pneumonia, compared with short fe and rapid resolution in lobar pneumonia. Fever a consolidation persisting over a period of two we indicated broncho-pneumonia. In many cases differential diagnosis was not difficult, but one clini type of pneumonia which was not uncommon presen difficulty—namely, that in which there was extens consolidation limited to one area of the lungs, type sometimes described as "confluent bronc pneumonia." These cases were especially frequ in the first year of life, were usually accompan by early empyema, and could in no way be distinguis during life from broncho-pneumonia.

Dr. McNeil went on to consider reasons w pneumonia was so frequent in the hospital class child under 2 years of age, and why it tended so of to assume the broncho-pneumonic type. He thou it possible that the causal organism might be differe but bacterial agency alone did not explain the h mortality and the incidence of the disease at a spe age-period, and amongst other functions the mysteri but powerful influence of constitution might play important part. It might be that the common ag in man, the pneumococcus, tended to produce in lungs of the youngest children a type of inflammat which was called broncho-pneumonia; that t tendency definitely weakened after two years,

s still evident until, say, five years, and that after at age the reaction changed to that extensive eolar exudation with little or no interstitial inflam-tion which was called lobar pneumonia. The luence of a natural age-constitution was not, wever, sufficient, for pneumonia was rare in healthy d well-cared-for children of any age. There must o be a deterioration of pulmonary function produced bad environment and hygiene, and the influence climate and season also came into play.

The Pathological Aspect.

Dr. AGNES MACGREGOR (Edinburgh) dealt with the hological aspect of the subject. Of 100 consecutive es of pneumonia examined post mortem at the yal Edinburgh Hospital for Sick Children, 81 were children under 2 years of age and 89 were cases of ncho-pneumonia; of the latter, 89 per cent. re bilateral, and 77·5 per cent. were of the confluent e and exhibited massive consolidation in at least lobe. In lobar pneumonia the freedom of the nective tissue framework and lymphatic system the lungs from inflammatory infiltration was a arkable feature. There was no persistent lym-ngitis, the inflammation was located in the alveoli, se walls possessed no lymphatics. The alveolar ta showed congestion, œdema, and desquamation pithelium, but the exudate was poured out into alveolar spaces and the walls did not suffer dis-anisation. When recovery occurred the products nflammation were removed by resolution. There no occasion for a process of reorganisation, h resultant permanent changes in structure and vitable disablement of function. In broncho-umonia it was usual to find a large amount of ammatory infiltration of the substance of the nchial walls and of the alveolar walls in the centre pneumonic patches. In the centre of an early on a bronchiole was present, with catarrhal tents in its lumen and inflammatory infiltration its walls and in the peribronchial lymphatics; he severer cases the infiltrating cells were mostly morphs. This area was surrounded by a group of solidated alveoli whose walls were also infiltrated; n infiltration of the walls seemed to precede solidation of the lumen, and extended beyond the e of the consolidated patch. It was therefore lent that infection reached these alveolar septa ugh the wall of the bronchus and along the alveolar a, and not by continuity of lumen. Acute inter-al inflammation was an essential part of the ess. She believed that the existence of progressive phangitis in broncho-pneumonia accounted for firm hold which the infection gained upon the gs, and that its absence in typical lobar pneumonia ured rapid and perfect recovery. The question ther all cases in which the features of confluent ncho-pneumonia were present at the time of death sessed those features from the outset was important nnexion with the problem of differential diagnosis bar and broncho-pneumonia during life, and the iculty of placing certain cases in one or other he two groups. It seemed not unlikely that the phangitis which led to broncho-pneumonia might elop either from bronchitis or from a localised h of primary pneumonia. In certain cases of lised pneumonia of the lobar type lymphangitis ht supervene as a later development, and lead to bsequent spread of inflammation throughout the gs after the manner of broncho-pneumonia. a case would be classed as confluent broncho-monia at necropsy. Some fatal cases of primary monia which clinically were thought to be lobar, at autopsy were found to be confluent broncho-monia, might perhaps be explained in this way. was widely recognised that broncho-pneumonia more apt than lobar pneumonia to cause serious age to the lungs and to be followed by various esirable results. Among the most important of e was suppuration, bronchiectasis, and fibrosis he lungs. All these might be directly attributed fects of lymphangitis.

In answering the question why the infection in broncho-pneumonia resulted in a massive invasion of the lung, Dr. Macgregor said that the most generally recognised condition which offered a possible explanation was that in these cases there were two infections, and that the primary fever was in some sense a preparation for the subsequent inroad of the pneumonia infection. The primary predisposed to the secondary infection. On the other hand, it should be recognised that in children broncho-pneumonia was often primary and without a preparatory antecedent infection. For the interpretation of these facts various suggestions had been offered postulating separately or together—(*a*) a virus of specific quality or of special virulence, and (*b*) a condition of the patient non-infective and yet preparing the way for pneumonia. In favour of the latter suggestion was the fact that it still maintained, though in a new form, the general principle of predisposition in broncho-pneumonia. The conditions advanced on this hypothesis were such as: (1) age less than 2 years, (2) bottle feeding, (3) under-growth, (4) poverty, (5) lack of care in upbringing, and (6) rickets.

Diagnostic Criteria.

Prof. LEONARD FINDLAY (Glasgow) said that there was no difficulty in diagnosing cases of secondary broncho-pneumonia, but primary broncho-pneumonia was quite a different proposition. In the past he had tried to decide on the clinical features, but had found that cases which during life had been diagnosed as lobar pneumonia were discovered post mortem to be broncho-pneumonia. He had therefore come to regard age as the chief diagnostic criterion, because apparently lobar pneumonia was never found post mortem in children under 3 years of age, and he had come to the conclusion that all primary cases under that age were broncho-pneumonia. In children over 3 years of age primary pneumonia was almost invariably found to be, at autopsy, lobar in type. From January, 1925, to March, 1926, all the cases dying of pneumonia in his wards had been examined pathologically. The criteria used for the diagnosis of broncho-pneumonia were those given by Dr. Macgregor—namely, bronchial infection, involvement of interstitial tissues, and comparative scarcity of fibrin in the exudate. Of a total number of 65 cases examined, 35 were examples of primary pneumonia under the age of 3 years, and of these 15 were typical broncho-pneumonia; in 14 cases the clinical characteristics and the gross appearances were those of lobar pneumonia, but histological examination proved them to be broncho-pneumonia. In five cases it was difficult to decide, but they appeared to be of the mixed type, and only one case was lobar pneumonia. He had therefore come to the opinion that the prevailing type of pneumonia in infants was nearly always broncho-pneumonia. This was of great importance, because the infiltration of the interstitial tissues meant that bronchiectasis was apt to follow, since the most important factor in the causation of bronchiectasis was fibrosis. As regards the cause of this special type of inflammation he thought that the host was a more important factor than the virus.

Lieut.-Colonel W. GLEN LISTON (Edinburgh) spoke on the bacteriology of the cases referred to by Dr. McNeil. He emphasised the difficulties of bacteriological investigation in respiratory cases, and also the similarity of the naked-eye appearances of the lungs to those seen in the influenza epidemic, and therefore he made use of a special influenza agar culture medium. Culture tubes were inoculated with material taken by lung puncture post mortem, and many of these showed a pure growth of influenza bacillus. This organism was also present in large numbers in the sputum. Out of 33 post-mortem cases the influenza bacillus was isolated in 21, and of these 21 cases all but two were broncho-pneumonia. He came to the conclusion that to isolate the influenza bacillus it was necessary to use a special medium, that the bacillus was liable to attack young people, that it could cause definite lesions in the absence of

other organisms, that it opened a path for secondary infection, and that the high death-rate of broncho-pneumonia was due to the presence of the influenza bacillus, although that organism might be isolated from cases which were not serious.

Treatment.

Dr. HUGH THURSFIELD (London) wished to deal with a different aspect of the subject from previous speakers—namely, that of treatment. He had come to the conclusion that there was no material advantage in attempting to distinguish between broncho-pneumonia and lobar pneumonia in children under 4 years of age, since nearly every child dying of broncho-pneumonia showed patches like lobar pneumonia, and it was often possible to demonstrate lobar and broncho-pneumonia in the same lung. In discussing the organism responsible for pneumonia it must be remembered that practically all the complications of primary broncho-pneumonia were due to the pneumococcus, and for the purpose of treatment it was necessary to assume that pneumonia was one disease and due to one organism. With regard to the preparation of the lung for the reception of the pneumococcus, he could not accept the view that all bacilli resembling *B. influenzæ* were, in fact, the Pfeiffer organism; in many cases they were the Bordet organism. The treatment of pneumonia had for many years remained unchanged, and, therefore, he came to the conclusion that it was advisable to try specific methods. With regard to antipneumococcal serum, it was costly, had to be given intravenously every day—a matter of great difficulty in young children—and even so it only dealt with one type of pneumonia. For the last three or four years he had used vaccines in every case of severe pneumonia. The vaccine used was a stock pneumococcal vaccine sensitised by the addition of rabbit's serum. He gave 50 millions of this vaccine on the first day, 100 millions on the second day, and 250 millions on the third day. Of 126 cases of pneumonia which had come under his care, 99 did not receive a vaccine. The average age of these unvaccinated cases was 2 years 8 months, and 28 died; 58 were under 2 years, and of these 24 died. 27 cases received vaccine treatment, their average age being 2 years, and four of the cases died. The number of vaccinated cases under 2 was 13, of whom four died; and over 2 years of age, 14, all of whom recovered. Although he did not claim that these figures established any proposition they were encouraging, and there was a slight improvement in the mortality of the two groups of cases treated with vaccine methods. It must be remembered that only the severe cases were given vaccines, and his impression of the results obtained was that the condition of those that had received vaccines 24–48 hours after the injection was better than would have been expected if they had not been treated with vaccine. One case, a very severe one complicated by empyema, was treated by immunotherapy with excellent results. In conclusion he pleaded for a further trial of specific therapy.

Dr. NORMAN CARMICHAEL (Edinburgh) said that it must be admitted that there were two definite types of broncho-pneumonia, primary and secondary. The secondary type was not difficult to diagnose, but the primary cases were. These were cases of patchy nodular broncho-pneumonia which closely simulated lobar pneumonia, and it was practically impossible to differentiate between the two conditions. In vaccine treatment it was a great help to give the vaccines early, and, therefore, an early diagnosis was important. Everyone agreed that the secondary cases were due to mixed infection; the primary cases were due to the pneumococcus complicated in a few instances by Pfeiffer's bacillus. He thought also that the pneumococcus might vary in different types of lobar pneumonia—e.g., in the pneumonias of older children, particularly of the cerebral and abdominal type. Was it not possible that the pneumococcus had different types comparable with paratyphoid organisms, and that each type had its different manifestation? He thought that advance in the knowledge of pneumo would lie along bacteriological and serological lines

Dr. C. P. LAPAGE (Manchester) said that m pneumonia, especially in infants, was of the favo able type, and he thought it was necessary to ha further search before abandoning the view th croupous pneumonia was uncommon in childho Clinically it was possible to give a definite progno the dry type being a favourable type. The nature the pneumonia was determined by (*a*) predispositi the weak and debilitated child being more lia to infection; (*b*) the chance of infection; (*c*) route of the disease; and (*d*) the mixture of germs, particularly the influenza bacillus. He not use serum because the results were so g without it.

Dr. P. F. ARMAND-DELILLE (Paris) drew attent to the value of fluoroscopic examination in the diagn of lobar and broncho-pneumonia in small child In lobar pneumonia associated with a high temperat and a short course, possibly without physical sig there was to be found in one lung a pyramidal shad with its base at the pleural surface; whereas, broncho-pneumonia with irregular temperature, lungs were not quite as clear as normal, but there no definite shadow such as occurred in the lobar ty

Two Incompatible Propositions.

Dr. H. C. CAMERON (London) drew attention to dilemma in which the discussion had so far landed meeting. Two quite incompatible propositions been put forward. First, that it was not important distinguish between broncho-pneumonia and lo pneumonia, because such distinction was impossib and secondly, that the frequency of lobar pneumo was small but that the prognosis was invariably go The figures produced from Edinburgh and Glas were quite different from each other, but su it was true that lobar pneumonia did occur and t it was the same disease from old age to childho but that its virulence gradually became less. The f and most characteristic sign of lobar pneumonia what would be expected—namely, dullness.

Dr. C. W. VINING (Leeds) said that clinically th were two clear-cut types of pneumonia, in one which the prognosis was excellent. He thought t empyema was more liable to follow lobar than bronc pneumonia. The value of treatment was v difficult to assess because the cases did so well. laid importance on fresh air and continuous inhalati of oxygen, particularly in bad cases of bronc pneumonia. He also thought that the giving of la quantities of milk was a mistake; the child sho be given plenty of fluids to drink, and carbohydra but not milk.

Dr. WILKIE SCOTT (Nottingham) had used vac treatment for six years with very good results. vaccine used was Wynn's vaccine, and the course the disease in cases treated with it was shorter t those before vaccine treatment was used. He also used subcutaneous administration of oxy but did not think it had been of any help; he c used it in bad cases.

The PRESIDENT commented on the amaz mortality of pneumonia in infancy, and pointed that pneumonia was surely a general disease wit specific manifestation in the lung. To him bronc pneumonia suggested symbiosis, whereas in lo pneumonia there was a blood infection. Comment on the value of immuno-transfusion he said thought that this form of treatment had a very g future.

Dr. HELEN MACKAY (London) thought that s methods should be adopted to lessen the incide of broncho-pneumonia. If the incidence of colds w diminished then the incidence of broncho-pneum would also be diminished. In Vienna the result giving cod-liver oil to children during the wi months was that the incidence of colds was diminis

had no figures to prove this statement, but those e her impressions.

THURSDAY, JULY 21ST.

n the second day the subject of discussion was TE INTESTINAL OBSTRUCTION IN INFANCY AND CHILDHOOD.

R. ALEXANDER MACLENNAN (Glasgow) said that symptomatology was much the same as in adults. malady was a fatal one unless relieved; prognosis in children might be somewhat less ous than in those of maturer years, but as an offset his relative benignity must be placed the fact that nany of the obstructions due to congenital mal-nation relief was impossible. Children stood stinal obstruction comparatively well, for the on that the child's intestine was less prone to s than the adult's. In the main the disease was e at all ages, but obstructions due to congenital rmities were entitled to separate consideration. uodenal stenosis a complete stenosis was probably moner than one which was incomplete. A feature ll developmental obstructions was the tendency the bowel distal to the obstruction to be in a e of what might be described as embryonic ticity. Thus a functional atresia was super-osed upon the anatomical. It was to the former lition that the well-nigh hopelessness of the nosis must be ascribed. Fortunately, duodenal osis was very rare, and it was seldom diagnosed y enough for successful treatment. Indeed, it was om possible that any treatment could be curative, account of the non-distensibility of the jejunum g almost always, if not always, an accompaniment. symptoms upon which most reliance must be ed were early and persistent vomiting, with, in y cases, icterus. The operative repair of such a lition was one which would tax both the child and surgeon. Gastro-enterostomy and duodeno-jejuno-y were operations having a high mortality in nts, and the operation was practically doomed to re if it lasted more than 20 minutes. Other forms bstruction due to congenital deformities were nal and ileal atresia, colic obstructions, rectal ructions, exomphalos, Meckel's diverticulum, and ngulated hernia.

r. MacLennan said that to refer to all the various es of acute obstruction in children would be e, but reference might be made to one or two s which were frequently met with. It should be forgotten that the term "acute obstruction" h referred to symptoms was not synonymous "complete obstruction," and hence the dividing between acute and chronic obstruction was a broad Acute exacerbations superimposed themselves the chronic, and as in children the chronic state masked; clinically only the attacks of acute ruction were recognisable. Under this aspect he case came those obstructions which resulted a tuberculous infection of the mesenteric glands band-formation, or adhesions with kinking of bowel from a contracting cicatrix. These condi-s were often associated with a healed tuberculosis, they might crop up during the infective stage of astic peritonitis. How far the final stage in any onitis was due to obstruction was a point which t profitably be discussed. Symptoms indis-nishable from those produced by obstruction t be set up by other conditions without any ication of the lumen of the bowel. For instance, trangulated omentum, strangulated Richter's ia, and a mesenteric embolism would produce of symptoms almost incapable of differentiation a true obstruction. It was the general custom lassify intussusception among the obstructions, ntussusception was not more an obstruction than ndicitis was a general peritonitis. Intussusception be operated upon before it was obstructive, as an inflamed appendix before it gave rise to a ral peritonitis. The risk of leaving an appen-is until perforative peritonitis had developed was not nearly so serious as leaving an intussusception until obstructive symptoms set in. In intussusception, which was possibly one phase of the status lymphaticus, death was apt to be sudden and entirely unexpected.

The symptoms which resulted from the interruption of the intestinal flow, said Mr. MacLennan, were vomiting, visible peristalsis, and distension. Symptoms due to interference with function might be referred to under the following headings:—

(*a*) *Toxæmia.*—Considerable experimental work had been done to elucidate the results of the obstruction of the intestine which, although enlightening, had also added an element of complexity. The action of the chlorides, which were so quickly reduced in the circulation, had been proved to be of the greatest importance, but that their replacement was a desideratum was not yet established. Distension alone was serious from its pressure effects on the thoracic organs, its interference with deep respiration and with the heart. Clinical experience as well as scientific research showed emptying of the bowel to be essential.

(*b*) *Disturbance through the sympathetic* might explain some of the symptoms.

(*c*) *Paralysis of the Bowel.*—The changes in the circulation of the bowel and the reflex stimuli would account for the effusion of fluid which occurred almost invariably with any obstruction.

(*d*) *Peritonitis from Perforation.*—As the result of gangrene this serious catastrophe might set going its own series of symptoms, but as a rule death took place before that occurred.

Referring to treatment, Mr. MacLennan said that the stomach should be washed out early in the anæsthetic period, great care being exercised that none of the stomach contents found their way into the trachea. After opening the abdomen, distended bowel should be avoided and a gentle search for undistended gut instituted, the obstruction being approached from the sound side. After the obstruction had been relieved, if anything further were required the surgeon was often placed in a dilemma whether to resect, perform a lateral anastomosis, or to be content with an enterotomy. There did not seem to be any great reason why an enterotomy should not be done. He disliked making a fistula, but these fistulæ—in children at any rate—showed a great tendency to spontaneous closure if made through the omentum. The handling required in resecting was against its success, and so the quick methods of performing intestinal union were attractive. The possibility of adding infection to the already damaged abdominal contents was to be avoided at all costs. It was a decided advantage to leave as much saline in the abdomen as it would hold, and he thought the addition of 5 per cent. cane sugar, a half to one cubic centimetre of pituitary extract, and the same quantity of adrenalin was beneficial. The choice of an anæsthetic was most important. Most surgeons disliked chlororform for an intestinal obstruction, but where chloroform gained was in its greater power to produce muscular relaxation. An obstruction was more often associated with an alkalosis than with an acidosis; it was, therefore, possible that this general dislike of chloroform might not be an entirely sound doctrine. In this connexion the recent proposal to introduce pepsin and hydrochloric acid with saline into the peritoneum as a remedy in peritonitis might find support, and the almost invariable rule to give alkalis and glucose might sometimes require to be disregarded. The advice to give excess of sodium chloride might well receive a careful trial, not only because its quantity had been reduced, but also because it had a direct antagonistic action on the toxins developing in the distended bowel. The important item in the prognosis was the degree of ileus present, and this would depend to some extent on the amount of handling which had been found necessary at the operation, as well as upon the nature of the obstruction and the general robustness of the child. Where evisceration had been performed the prognosis was

bad. An early diagnosis, followed by prompt intervention, was still the thing which mattered most.

The Importance of Early Diagnosis.

Mr. BARRINGTON-WARD (London) said the factor of predominating importance in intestinal obstruction was an early accurate diagnosis. Nothing but surgery could avail and time was all-important. In most cases relief of intestinal obstruction in the early stages was a comparatively simple matter, in late cases the operation demanded the most expert and fortunate surgery. It was essential to be sure by an accurate reading of physical signs that intestinal obstruction was present. The cardinal symptoms were three in number: (1) abdominal pain, (2) vomiting, and (3) constipation. On examining the abdomen some voluntary rigidity would be noticed at first, and it might be possible to locate special tenderness in the region of the obstructed intestine. A little later distension was manifested and the abdomen became full and everywhere tender on palpation. There was never any true rigidity unless peritonitis supervened as a sequence to the obstruction. The surgeon's aim should be to diagnose and treat the case before any gross distension of the intestine became obvious. It was helpful to determine beforehand the nature of the obstruction. The age of the patient might assist, for at each period of life certain types of obstruction were more likely than others. If the obstruction occurred in the new-born it was likely to be due to congenital atresia or volvulus; if in infancy, to intussusception or an external hernia. In childhood obstruction by bands, Meckel's diverticulum, or the appendix vermiformis, and volvulus of the small intestine occurred most frequently. He proposed to confine his remarks to some of the rare accidents to children of later years, of which instances had recently come to his notice. He referred to three varieties of internal hernia. First, a congenital hole in the mesentery through which strangulation of the intestine might occur, a rare but interesting form of intestinal obstruction; secondly, diaphragmatic hernia, either traumatic in origin and due, as a rule, to motor-car injuries, or congenital, in which case the condition was usually recognised before obstruction occurred; thirdly, retroperitoneal hernia. The diagnosis of all these cases as obstruction was easy, but diagnosis of the kind of obstruction was well-nigh impossible. In volvulus of the small intestine there was nearly always a history of previous minor attacks; there was severe colicky pain followed by vomiting. The bowels might be regular or slightly constipated. The abdomen at first was not distended, but later when strangulation of the small intestine was complete, abdominal distension occurred. Evidence of profound ketosis was always present, the breath smelt of acetone, and acetone was found in the urine. The diagnosis was not easy but obstruction was often incomplete and recoverable, and the history of the previous minor attacks which corrected themselves unaided might put the observer off his guard. Volvulus had been wrongly diagnosed as abdominal tuberculosis, but more frequently as ketonæmia. In ketonæmia the patient suffered from severe vomiting, drowsiness, sometimes restlessness, constipation, and at times abdominal pain, and the bowels were inactive. The chief point in the differential diagnosis was the nature and character of the pain. In ketonæmia the pain followed the vomiting and was the result of the violent efforts of the abdominal muscles; in volvulus the pain was the first symptom, was always severe, and preceded the vomiting.

Nearly all the problems of treatment, said Mr. Ward, were concerned with late cases. He agreed with Mr. MacLennan that intussusception was not in its early stages a form of intestinal obstruction; there had been recently a tendency to revert to the old methods of injection or inflation as a curative procedure or as an adjuvant to operation. As to the management of the irreducible segment there was still a considerable difference of opinion. Immediate resection and union carried no doubt a high mortality but he thought it was preferable to measures t included temporary drainage of the intestine, wh the child rarely survived.

Obstruction in Acute Intussusception.

Miss G. M. HERZFELD (Edinburgh) based remarks on a series of cases of acquired intesti obstruction seen during the past seven and a half ye at the Royal Edinburgh Hospital for Sick Childr These numbered in all 160 cases, 116 being cases acute intussusception, 16 of obstruction due abdominal tuberculosis, 22 of irreducible and stran lated hernia, and 6 of obstruction occurring as post-operative complication in cases of acute suppu tive appendicitis. The main point of differe between acute obstruction in infancy and childh and that of adult life was that in children the abdo inal distension was often less apparent. The lad pattern was seen typically in cases of chronic obstr tion, but it should be remembered that in an emacia child peristalsis and ladder pattern might be no from time to time without definite obstruction. the treatment of all cases of obstruction in infa and childhood pre-operative care was of utmost importance. Children stood dehydrat very badly, and in every case much fluid was l and very little absorbed. Without exception, the fore, the loss of fluid should be made good, prefera by subcutaneous glucose saline. If fæcal vomit were present it was advisable that gastric lav should be carried out as a preliminary to operati The best anæsthetic was open ether, combined w local infiltration with novocaine; recently M Herzfeld had used spinal anæsthesia in cases of int susception with uniformly good results. In the p operative treatment warmth and abundance of fl were the most important points. She wished to di from the statement made by Mr. MacLennan that intussusception the obstruction was definitely seco ary and that its classification under obstruction mi lead to delay in operation. In her experie obstruction was complete in the majority of ca within the first three or four hours and a clini picture of obstruction was marked from the fir whereas the special features of intussusception, ac abdominal pain, and the passage of blood per rect might not be so easily noted. It was only in ra cases of chronic intussusception occurring in ol children that the lumen of the bowel might rem more or less patent throughout the illness. In typical intussusception of early infancy compl stoppage was the rule at a very early stage. question of recurrence of an intussusception was interest; she had met with seven instances. W regard to the treatment of irreducible cases thought that everyone was now agreed that resect and anastomosis offered the best prospect of cure.

Mr. N. M. DOTT (Edinburgh) raised two poin first, that children suffering from acute intesti obstruction tolerated operations, given a good an thesia, up to one hour's duration very well, and it v open to question whether the loss in delicate a accurate technique did not nullify the gain of a v short operation-time; secondly, that resection v possibly the best treatment in certain cases whi though reducible and viable, were extremely difficult reduce and in which the bowel was severely bruis In support of this theory he instanced a series 20 cases of acute intussusception treated during past two years. The results appeared sufficien satisfactory, and from them he was led to pl meticulous care in technique before the time-factor operation for these conditions. He believed that to absorption from the tissue of severely bruised bo might be a cause of death.

Dr. H. C. CAMERON spoke of the need for ea diagnosis when confronted with the grave sympto of intestinal obstruction in a new-born infant. duodenal obstruction the diagnosis could only made by an X ray examination in the first few d of life. There was a tendency in these cases to w

child in a shawl and adopt a fatalistic inaction, one such patient with duodenal atresia operated by Mr. Steward made a complete recovery. With ard to acute intussusception, he called attention he contrast in practice prevailing in Scandinavia, re in 80 per cent. of the cases taxis through the ominal wall without laparotomy was successful. ondary laparotomy was necessary in the remaining per cent. Mr. Jennings Marshall had recently (in nall boy suffering from extreme ketonæmia with acteristic tonelessness of the abdominal muscles, had developed after some days of illness a com- ating intussusception) reduced the intussusception moment without difficulty. Without the keto- ia this would have been impossible. In the differ- al diagnosis of intussusception from follicular colitis Henoch's purpura he thought it was a help to note smell of the blood-stained evacuation, odourless ntussusception, very foul-smelling in the others. ly, he spoke of the immense value of blood trans- n before submitting a young and ill infant to ation.

r. C. P. LAPAGE dealt with points in diagnosis. ssusception should be recognised early and if ible before blood appeared in the stools or even on inger after rectal examination. Sudden spasms of minal pain beginning in a previously healthy child, recurring at increasingly frequent intervals and increasing severity were practically diagnostic. s of acidosis on account of the previous attacks not so difficult as cases of Henoch's purpura h sometimes only had a few purpuric spots on the of the buttock. The blood was more profuse in och's purpura than in intussusception, and often atient was very sensitive to rectal examination. rew attention to the fact that purgatives might ase the symptoms very much in obstruction s, and also emphasised the value of subcutaneous e injections as an aid to withstanding the opera- In support of operation in the early days he ed a case in which an infant of a few weeks old r his care had successfully withstood a long minal operation in which his colleague, Mr. Morley, had removed a mesenteric cyst about ize of the child's own head.

. MARGARET TODD (Edinburgh) said she wished mphasise two points raised by Dr. Cameron. as to the difficulty of distinguishing between susception and acute enteritis; although it ed that this should be perfectly easy, yet her rience had been that it was not always so. It quite possible that a history of enteritis might de the onset of an intussusception; on the hand, one or two greenish motions might occur an intussusception, simulating a simple enteritis. second point she wished to emphasise was the rtance of transfusion, both as a pre-operative and operative measure.

FRIDAY, JULY 22ND.

the third day, in the absence of the President, senior Vice-President, Dr. CHARLES MCNEIL, ded over a discussion on

THERAPEUTIC MODIFICATIONS OF THE DIET IN INFANCY.

. H. C. CAMERON (London) said that debates nfant feeding seldom aroused a profitable dis- on, and as a rule served only to make clear the ifficulty of reconciling the views of those who might pposed to speak with authority. Therefore, in irst place he would ask the question, Wherein he difficulty and complexity of the subject? was it that on this subject, whose importance generally admitted, opinion remained so fluid, o little that was solid and concrete had crystallised it? Why was it that in practice one still ntered, on the one hand, a frenzied search among st of proprietary foods for one which would act the promises of all, or, on the other hand, a igid adhesion to some one system of feeding te the persistence of symptoms?

It was mercifully the nature of the child to wax and grow strong, and this upon a very great diversity of dietetic prescriptions. The human infant, however, was of so sensitive a nervous organisation that a great variety of adverse circumstances were capable of ill-effects upon its health, effects which almost always manifested themselves in gastro-intestinal and nutritional disturbance. The infant had but one function highly developed—namely, the digestion and the absorption of food. So hypertrophied a function was necessarily unstable, and, in the absence of other functions capable of manifesting symptoms of derangement, disorders of very different kinds were apt to show themselves in the guise of digestive and nutritional disturbance. Because of the action of one or other of these adverse influences many dietetic prescriptions, in themselves admirable, were apt to fall into disrepute, and to bear the blame of a disturbance of which they had not been primarily the cause. On the other hand, since those influences were more often than not transitory in their action, many dietetic recipes tried at the moment of recovery bore off the credit for a recovery which was, in fact, unconnected with their use.

Such difficulties, said Dr. Cameron, were inherent in the study of the infant and its diet, but in this country at the present time there were other difficulties to be contended with which were responsible in part for the confusion which surrounded the subject. He would refer to three only, the first being a neglect of the study of pædiatrics in universities and medical schools. At these places too little attention was paid to the scientific study of the child. The subject was regarded as a specialty, and struggled painfully for recognition among the conflicting claims of oto-rhino-laryngology, orthopædics, and even proctology. It was certain that only when pædiatrics had been elevated to the rank of a subject of the first importance, and had taken its place with medicine and midwifery as one of the trilogy of the final examination, would the profession as a whole be equipped, as it should be equipped, to deal with so all-important a branch of general practice. Operative surgery, on the other hand, which to-day occupied so large a part of the student's time and attention, belonged rightly to the specialties; its practice was a matter for post-graduate rather than undergraduate study, and its technique could only be usefully acquired by the special training of some of those who had already received a medical education. The dearth of professorial chairs in pædiatrics in this country was symptomatic of, and productive of, the widespread neglect of the subject.

The Dangers of a Standardised System.

Secondly, said Dr. Cameron, there was the detrimental effect of the advertisement of proprietary foods. Digestive derangement, however caused, was taken as indicating that the particular diet adopted was responsible for the disturbance, and a change was demanded. One food after another might be tried in an unmethodical search for something which "suits." The numerous advertisements for proprietary foods were cleverly designed to play upon the anxieties of the mother. Their effect in producing this constant demand for change was not to be set aside. These foods were to some extent the raw materials of the physician's art. Their virtue lay in the uses to which they were put, not in their composition. Many owed their origin to successful prescriptions in the past for particular types of disturbance. Thirdly, there were ill-effects from misunderstanding of propaganda for infant welfare. The appreciation of the disastrous effect of these repeated and injudicious changes of diet in the dyspeptic disturbances of infancy had led some to go to the opposite extreme, and to maintain that by a rigid adhesion to some particular formula, or scheme of feeding, success could always be obtained, at least in what was called a "well" baby. Propaganda upon matters of health was by no means free from danger to the public. For popular consumption

propaganda must be so simplified that the truth was almost squeezed out of it in the process. An outline, a mere diagram, was all that could be depicted, without light or shade, without degrees of emphasis, and without consideration of exceptions or variations. Hence the successful propagandist was seldom himself an expert. If it were possible to feed all infants, healthy or sick, in the same way, the subject could have no possible interest for medical men. Indeed, under a standardised system it was not necessary before giving advice to see the infant at all. Thus in one of the largest institutions for infant welfare it was considered possible to manage the whole business by letter, and the matron conducted a consultation department known as "better babies by post." From all over the country mothers wrote describing the symptoms from which their babies suffered, and the questions and answers were published in the lay press. The child might be over-fed or under-fed, it might have pyelitis, it might be suffering from injury to its medulla oblongata at birth—no one knew. But the advice by post, a little stereotyped perhaps, simple and legible, was always to be obtained.

In the last 20 years much progress had been made in the attempt, based upon the study of the ætiology of particular symptoms, to devise modifications which might suffice to control and correct disturbances originating from a standard diet. In other words, if the sighting shot was unsuccessful one must seek to determine the nature of the error and how it could be corrected. No doubt these therapeutic diets were for the most part to be regarded only as temporary expedients, and the ultimate aim must be to restore the child as quickly as possible to the standard diet of health. Only when it had demonstrated its power to thrive on a standard diet could complete success be claimed. Dr. Cameron exhibited a series of charts showing the value of three such dietetic modifications. (1) High caloric feeding in post-infective dystrophy. In the search for a high caloric feed, he said, he had used Keller's malt soup in children over four months old and had found it most valuable, but he had obtained better results in young atrophic infants with lactic acid milk than by any other method. He had not used Karo syrup as an addition, as recommended by Marriott, but he had combined it with concentrated Benger's food. (2) Thickened feeding in vomiting of aerophagy, nervous vomiting, and hypertrophic pyloric stenosis. In these cases he gave solid food five to ten minutes before the breast or bottle was given, the result being to call forth the peristolic action of the stomach before the ordinary food was given and thus to prevent vomiting. (3) Feeding with a high percentage of casein in fermentative diarrhœa. In these cases, which might never occur in a breast-fed infant, the child had lienteric diarrhœa with green acid stools and excoriated buttocks, but the addition of casein produced an alkaline stool with constipation. He gave this in half-teaspoonful doses before or after food two to three times a day.

DR. DINGWALL FORDYCE (Liverpool) said that the only diet which did not require modification for therapeutic purposes was breast milk. The defects of breast milk were usually those of quantity rather than quality. He did not think that chemical examination of breast milk helped very much, but bacteriological examination helped sometimes, for in three cases he had by this means discovered infection of the milk with *Bacillus coli*. In regard to artificial feeding there was not one general best dietary, nor one which might not require alteration. In most cases of digestive disorder and in the post-infective dystrophies various forms of therapeutics had been tried with good results, but he would particularly mention the results obtained by thyroid treatment, though it was not usual for the exhibition of thyroid gland to be necessary. He said that successful treatment was impossible by following a rule of thumb, and although a diathesis might or might not be recognised, yet it was most essential that the constitution of the child should be studied; he reminded his hearers that many years ago Sydenham had shown there was a tender to particular constitutions which varied in terms years, a fact which was also restated by Sam West. Success in baby feeding could only be lea by soaking in the clinical aspect either in hospi or in the home. He hoped that if Dr. Camero suggestion, with which he was in entire agreeme of the appointment of professors of pædiatrics w adopted, the department instituted would be for t medical care of children, and not only for the the peusis and care of sick children. With regard to t special points raised by Dr. Cameron, he would ag lay emphasis on the endocrine treatment in the po infective dystrophies, because very important chan were produced in the thyroid by infections. He d not consider that it was necessary to give so food in persistent vomiting; the vast majority cases did well without resorting to this form treatment.

Quantitative Modification of Diet.

DR. G. B. FLEMING (Glasgow) said that Dr. Camero remarks on feeding had been concerned with qualitati and not with quantitative modifications. He hims wished particularly to discuss quantitative modifi tions, because children who were under-fed we progressively down-hill, but those who were ov fed soon rebelled. Infants were practically starv by many methods of feeding, and this he regard as the most common cause of malnutrition. T caloric requirements per kilogramme for a norm child aged 6–9 months were as follows: basal requi ments, 55 calories; to balance loss of excre 5–6 calories; for growth, 5 calories; and for muscu exertion, 35 calories; making a total of 100. Infan atrophy was not a disease, but was due to malnutriti This could occur in one of three ways: (1) the ch did not receive enough food, a common cause atrophy; (2) the food given was not utilised, t occurred in alimentary disturbances, pyloric steno &c.; or (3) the food given was extravagantly us a condition which in infancy occurred only in feb states. The atrophic infant had no difficulty in absorption of protein and fats, and once carbohydra were absorbed they were well utilised. There was alteration in the basal metabolic rate until one-th of the body-weight was lost, and after that the r steadily fell. A simple satisfactory rule was t for every 1 per cent. a child was below 65 per cent its expected body-weight, it should be given 1 cal per kg. less than the number of calories that would required for the expected weight.

DR. LEWIS THATCHER (Edinburgh) spoke of value of lactic acid milk, which he used more more as a standard diet for premature and debilita infants, and in wasting and infective disord Most atrophic babies were under-fed, and this met of feeding enabled a high calorie food to be used; value also lay in the debuffering effect of lactic acid. began by using skimmed milk, and gradually increa the amount of fat. Another advantage of the m was that it was possible to give with it a high p centage of carbohydrate. He showed charts illust ing the results obtained by this form of dietary debility, parenteral infections, and pyloric steno Only five feeds a day were given, and if carbohydra were not well tolerated by the mouth 200–300 c. of 6 per cent. glucose solution were given in peritoneally. He did not know how long lactic a milk could be continued, but if it was prepared the way Dr. Cameron described, out-patient moth could make the milk themselves, and in some cases had continued its use for months.

DR. L. G. PARSONS (Birmingham) said that agreed with previous speakers as to the value of la acid milk. The milk he used was soured by bacte means. The organism used was *Streptococcus lacti* and he thought the results were better than w chemically prepared milk. This method did however, lend itself to private practice, althoug was widely used in Canada in that form of practe

ll were agreed as to the value of lactic acid milk, but was a curious fact that fat absorption and calcium nd nitrogen retention were not so good as when rdinary milk mixtures were used, and calcium etention would not compare with that obtained y giving HCl milk. György, of Heidleberg, had ggested that the good results obtained were due the lactate-ion being synthesised in the liver to rbohydrate and glycogen. Skimming of lactic id milk was only called for if the child had diarrhœa. s a method of feeding in pyloric stenosis its value as second only to that of breast-milk, and its acidity elped to counteract the alkalosis which developed that condition, and which might prove a fatal mplication before or after operation.

Dr. C. W. VINING agreed that under-feeding was very common cause of infantile atrophy, and eaded for simple methods in the modification of od. He used the caloric value as a test whether fficient food had been given rather than as the means framing a diet; it was necessary to have some simple ethod to indicate to mothers the quantity of the od required. He had had excellent results with id milk, and also with the addition of banana pulp milk as recommended by Dr. Thursfield.

Dr. CATHERINE CHISHOLM (Manchester) said that e ideal was to restore the child to a normal diet soon as possible. She also used cultural methods the production of lactic acid milk, but she thought great endeavour ought to be made to get a breast-lk supply. With regard to banana pulp, her perience had been that for a time this gave excellent sults, but after it had been given for a long period olerance developed. She also had great difficulty getting babies to take thick feeds.

Dr. M. F. LOWENFELD (London) said apparently ere were two schools of thought about artificial eding. One was that exemplified by Truby King, ich attempted to humanise milk, and the other s the calorie school. She also drew attention to e fact that there were extraordinary variations in e quality of breast-milk. The percentage of fat pended on the amount of fluid in the breast and the gree of pressure put on the areola. Normal pressure the beginning, with maximum pressure at the end of tation, might produce a difference of 8 per cent. of , and it was for this reason that the vigorously king infant developed dyspepsia.

Dr. HELEN MACKAY drew attention to the fact that dried milks varied very much in bulk, and that the linary domestic measure might with one form of ed milk result in the production of a milk very much re concentrated than others. She usually gave a d containing 20 calories per ounce, so as to make a all feed. If it were essential to give a more concen-ted feed she gave 30-40 calories per ounce, but child might then take more food than was necessary order to get sufficient fluid to satisfy its thirst.

Dr. C. MCNEIL said that his experience of lactic d milk had also been a good one, and that the dency in milk modifications now appeared to towards quantitative rather than qualitative dification.

ERRATUM.—The Ichthyol Company point out to hat in our notice of special drug exhibits at the recent ting of the B.M.A. in Edinburgh a confusion has been le between ichthyol and ichtholan. Ichthyol is the material of various preparations, and the error consisted placing the percentages against ichthyol instead of inst ichtholan. The note should have read: "Ichthyol ichthyol preparations including ichtholan a 10 per cent., per cent., and 50 per cent. ichthyol salve with equal s of vaseline and lanoline."

EAST HAM'S EFFORT.—In order to claim a further nt of £2000 promised by the King Edward's Hospital d, the sum of £15,000 must be raised during the next months for the East Ham Memorial Hospital, the building hich is making rapid progress. There will be accommoda-for 80 beds, and the cost, including furnishing, will be 000, which is a heavy sum for a poor locality to raise.

Reviews and Notices of Books.

A TEXT-BOOK OF MEDICINE.

By American Authors. Edited by RUSSELL L. CECIL, A.B., M.D., Assistant Professor of Clinical Medicine in Cornell University. London and Philadelphia: W. B. Saunders Company. 1927. Pp. 1500. 40*s*.

THIS large volume may claim to represent modern American views on medicine, since it is compiled by 130 contributors, of whom the majority are actively engaged in practising and teaching in the United States. It begins with an account of the common cold, and then goes on, by way of influenza, to other infectious diseases. Such a sensible start at once encourages the reader, who will not be disappointed, for this book maintains a very high level throughout its pages. If we compare it with corresponding text-books in this country, one aspect of American medicine immediately comes to light. In the section on tuberculosis, for example, almost every portion is good, but according to our ideas too little space is allotted to the physical signs of the pulmonary form of the disease. It is true that the author of this section, Dr. Lawrason Brown, attempts to disarm criticism by stating (p. 216) that "the diagnostic value of physical signs has been greatly overrated," but this does not seem to be sufficient justification for allotting one page to this means of diagnosis as compared with more than three to the examination of the sputum. It may be that the stethoscope will eventually be discarded in favour of reports from radiologist and pathologist, but this time has not arrived. Other small points call for criticism. There is no mention of urinary diastase in the section on diseases of the pancreas (p. 771). Under the heading, "new growths of lung" (p. 823), only malignant tumours are dealt with; innocent intrathoracic tumours certainly receive attention in various pages, but they would be better grouped all together. The ætiology of uræmia is incomplete, no mention being made of the vascular factor; the description of the treatment of cerebral hæmorrhage and thrombosis (p. 1305) is not very good, not sufficient emphasis being laid on the value of lumbar puncture; and, lastly, the section on birth injuries of the central nervous system is hardly fair to the section of opinion which attributes the lesions to faulty development (p. 1329).

These criticisms apart, the book is really good and certain portions are excellent, notably the section on the ætiology of rickets, by Dr. A. F. Hess (p. 553). The section on the nervous system, edited by Prof. Foster Kennedy, starts off with syphilitic affections, and is very well planned throughout. The article on pernicious anæmia is very good; to this the only English author, Dr. A. G. Maitland Jones, contributed. The index, a most important part of such a text-book, is exhaustive, covering 50 three-column pages of small print. Great care has been taken with the dove-tailing together of the various contributions into a compact whole, and the book is a worthy production of the modern American school of medicine.

DISEASES OF THE NEW-BORN.

By JAMES BURNET, D.M., F.R.C.P. Edin., Lecturer on Diseases of Children, Royal Colleges, Edinburgh. London: Humphrey Milford, Oxford University Press. 1927. Pp. 275. 6*s*.

THIS book is intended as an elementary guide to students and practitioners, which shall aid them in the recognition of such diseases and abnormalities as are met with in new-born infants and in the first month of life. Special points in the anatomy and physiology of the new-born infant are described in the first two chapters. A book on this subject must necessarily be concerned to a considerable extent with structural abnormalities and defects; these are

depicted shortly and concisely in relation to such symptoms as they may cause. An excellent chapter on cardiac defects presents the differential diagnosis of congenital heart lesions very clearly. The ætiology and treatment of pyloric stenosis are discussed somewhat fully, and stress is laid on the importance of the distinction between this condition and pylorospasm. Cerebral lesions scarcely receive the attention to which they are entitled; the value of the book would be increased if some of the recent work on spastic birth palsies were included in subsequent editions.

There is undoubtedly a need for a book of this kind; it should be useful to all who are engaged in infant welfare work, and may be specially recommended for the use of students during their midwifery course.

THE NEUROSES OF CHILDREN.

Die Neurosen des Kindesalters. By Dr. W. CIMBAL. Berlin and Vienna: Urban and Schwarzenberg. 1927. Pp. 509. M.15.

IN this book Dr. Cimbal has made an ambitious attempt to deal with all phases and degrees of nervous and mental abnormality in children. To some extent he has been justified by the result; his account is unhampered by distinctions between structure and function, the symptomatology is admirably depicted, and controversial questions, such as the relative preponderance of hereditary and environmental factors—as far as neuroses are concerned—are discussed in a balanced and open-minded manner. The influence of endocrine function on physical and mental development receives full attention, and the author's account of it contains much that is of speculative interest, though hypothesis is occasionally presented as fact. Dr. Cimbal appears to accept the James-Lange theory of the rôle of the vegetative system, which will render some of his views on the physical aspect of neuroses unacceptable to many readers in this country.

A considerable part of the book is devoted to retardation and difficulties of education. This part is certainly the least successful. The author rigidly excludes the conception of innate subnormality, and pays little attention to any element of primary amentia which may be present. The classification which results from this attitude is so lengthy as to be almost unintelligible, while little assistance is given on the important and difficult problem of the selection of cases for treatment according to prognosis and degree of educability.

DISEASES OF THE PROSTATE.

Traité des Maladies de la Prostate. By GEORGES LUYS, Ancien Interne des Hospitaux de Paris. *Prostatectomies et Tumeurs Malignes.* By VICTOR PAUCHET, Chirurgien de l'Hôpital Sainte-Michel. Paris: G. Doin et Cie. 1926. Pp. 680. Fr.90.

THIS is a large treatise on diseases of the prostate written by an author who has specialised on per-urethral methods. Good accounts of the anatomy, physiology, and pathology of the prostate are given. The bulk of the work is concerned with benign enlargement. Better accounts of the problems to be faced by the urologist dealing with the disease can be found elsewhere, but the description of forage as a method of treatment is unique. M. Luys has carried out this procedure in 110 patients with almost uniformly good results. Nearly always the operation is conducted under local anæsthesia, but an essential condition is that the urethra should have been prepared by previous full dilatation with steel bougies. The actual electro-coagulation can never be completed under three or four sittings. The method is obviously a difficult one and requires much practice with intra-urethral instruments. There seems to be only one real contra-indication—namely, great size of the adenoma. The technique of removal of the prostate by suprapubic and perineal methods is well described and illustrated by Victor Pauchet, who states that h employs the perineal method in 35 per cent. of hi operations and the ischiorectal approach in 5 pe cent. This surgeon, who also contributes the chapte on the malignant prostate, claims 50 per cent prolonged cures, without any trouble or fistula per sisting, in ten cases of cancer.

The book is well worth reading by specialists i urinary diseases.

MANUAL OF SURGICAL ANATOMY.

Third edition. By LEWIS BEESLY, F.R.C.S. Edin. Surgeon, Craiglockhart Hospital and Hospital fo Diseases of Women, Edinburgh; Examiner i Anatomy, Royal College of Surgeons, Edinburgh and T. B. JOHNSTON, M.B., Ch.B., Professor o Anatomy, University of London, Guy's Hospita Medical School. London: Humphrey Milford 1927. Pp. 563. 18*s*.

THE call for new editions and reprintings of thi book testifies to its popularity. A comparison wit the former edition reveals only a few changes, bu all that was necessary to bring the book fully up t date has been done. It is easy to read, beautifull printed and illustrated, and presents anatomy to th reader from those points of view which are of specia interest and help to the surgeon. It is perhaps a little long for the undergraduate student, but coul not be abbreviated without losing considerably in it appeal to the operating surgeon. In its present for it fulfils the needs of both. We know of no bette English treatise on surgical anatomy.

DISEASES OF THE SKIN AND SYPHILIS.

By ALBERT STRICKLER, M.D., Professor of Derma tology and Syphilology, Temple University Depart ment of Medicine. London: Stanley Phillip Philadelphia: F. A. Davis Co. 1927. With 21 illustrations. Pp. 689. 34*s*.

THIS comprehensive text-book is obviously the wor of an experienced teacher, and contains severa original features. It includes many tables to assis differential diagnosis, and every prescription for a application containing drugs for local use is sub stantiated by an explanatory adjective in italics clearly explaining the exact purpose of each ingredient This is an admirable innovation, and one which migh well be adopted by the writers of future text-book in this and other branches of medicine. The basis o classification is simple, and follows ætiological fact and considerations in so far as these are establishe The many original and striking illustrations from actua photographs, without which no dermatological text book would long survive, will make a special appeal t the practitioner and to the student with an examinatio pending. The text is concise both in thought and i expression, and yet dogmatic assertions are avoide The long chapter on syphilis and other diseases of th skin caused by spirochætes is well conceived an profusely illustrated. The sections on treatmen fulfil all the requirements of modern dermatology The book is not too bulky and the index is adequat In fact, the very high standard set by dermatologica text-books that have made their appearance i America in recent years has been fully maintained.

PHYSIOLOGY OF REPRODUCTION IN THE COW.

By JOHN HAMMOND, M.A., Institute of Anima Nutrition, Cambridge School of Agricultur Cambridge: University Press. 1927. Pp. 226. 21

THIS will be found a most valuable work of referenc for advanced students and research workers i veterinary and agricultural science. The text of th book was written in 1922, but the most importan papers which have appeared since have receive mention in the addendum. Mr. Hammond not onl gives the results of his own researches, but compar

is findings with those of many other workers. The aterial upon which the author's work is based and he methods he relied upon are set out clearly in the troduction. The chapter on the breeding season cupies three pages, that on the œstrus cycle nearly 0 pages. Forty-six pages are devoted to pregnancy, d sterility occupies 11 pages. The sections on the atomical and histological changes reveal an enormous nount of painstaking research.

The author states that his study was undertaken ith several practical objectives in view, and mentions one of these a basis of knowledge for the rational eatment of sterility. There is much need of further vestigation into the pathology of sterility in animals. a recent article on the Treatment of Sterility the Cow[1] MM. Roger and Ricaud point out that erility in the cow is still very obscure, and refer to e need for more knowledge of the physiology and thology of the genital organs. Mr. Hammond has ade no direct investigation of the causes of sterility it has certainly advanced our knowledge of the ysiology of reproduction. The pathology of repro- ction seems to be a matter which might well become e subject of special study by one or more of the terinary schools and research institutes.

The book is profusely illustrated. There are plates showing a large number of original photo- aphs and microphotographs; the value of these uld have been enhanced by more detailed scription. The bibliography contains 400 references wn to the year 1926, and provides material which y be of considerable use to advanced students of erinary and agricultural science as well as to those ose interest is in the mammalian process of roduction.

JOURNALS.

QUARTERLY JOURNAL OF MEDICINE.—The July mber contains the following articles: Intracranial morrhage in Infancy and Childhood, by W. P. H. eldon. The post-mortem records of the Hospital Sick Children, Great Ormond-street, since 1860 w 50 cases of intracranial hæmorrhage in children der 12 years of age. The bleeding was extra- ebral (meningeal) in 28, and intracerebral in of these cases; none of the hæmorrhages was natal, but five were probably produced during our or birth. The most notable conditions with ch the hæmorrhage was associated were blood ases, malignant endocarditis, trauma, meningitis, pneumonia. One case was associated with oping-cough. The article is illustrated by two es, showing the appearance of the brain in five es.—The Sedimentation Rate of Erythrocytes in ain Tropical Diseases, by H. B. Newham. Obser- ons were made in such tropical diseases as sprue, entery, kala-azar, malaria, ulcerating granuloma leprosy, and in certain non-tropical conditions. the majority of tropical diseases an increased mentation rate was found. The author considers there is evidence that all cases with an increased mentation rate have a concomitant derangement ne liver. The sedimentation rate was not found to elated to any special blood group.—The Limitation fuscular Effort and its Relation to Cardiac Failure, A. E. Clark-Kennedy and Trevor Owen. These resting observations will be dealt with later in columns.—Observations on the Serum Calcium ulmonary Tuberculosis and on Treatment by avenous Injection of Calcium, by William Brock- k. Estimation of the blood calcium in 70 cases of nonary tuberculosis did not show any very con- rable deviation from the normal, the tendency g for a fall in the acute cases and a rise when the ase was healed. Intravenous injection of calcium found to raise the blood calcium temporarily for it 48 hours, and in six cases thus treated by ated injections encouraging results were obtained. ultiple Nodular Hyperplasia of the Liver, by L. E. Hurley and G. R. Cameron. Cayley, in 1883 first described this condition, under the name of subacute atrophy of the liver. The liver becomes small and nodular, and the disease may be mistaken for portal cirrhosis or for adenoma of the liver. The cause is unknown, but it is presumably a toxin. Two fatal cases are described, with post-mortem reports and plates illustrating the histological features of the livers. The characteristic changes in the latter are the regeneration of liver cells and the formation of new bile-ducts.—The Diagnostic Value of Dextrose-tolerance Curves, by R. Hale-White and W. W. Payne. A series of sugar-tolerance curves were made on normal and diseased people. It was found that only one type of curve is diagnostic, the diabetic type, in which the fasting blood-sugar, the height of the peak and the time of return of the blood-sugar to normal are all abnormal. In other diseases a diagnosis cannot be made on the sugar-tolerance curves alone.—Studies in Blood Coagulation and Hæmophilia. I. Blood Coagulation in Hæmorrhagic Diseases, by Ronald V. Christie. Observations on the coagulation times of successive drops of blood taken from a single puncture show that they diminish with each drop, and then remain stationary. The first drop gives the coagulation time of the blood, the second or third drops indicate the effect of the tissue reaction (liberation of a thromboplastic substance), and the subsequent drops are an index to the platelet reaction. In purpura there is a marked diminution in platelets, but the coagulation time remains unaffected. Curves of the coagulation time of successive drops of blood in purpura indicate that the platelet reaction is practically absent. It is probable that in addition to the diminution of the platelets, a toxin must also be present to produce purpura, and that in jaundice this toxic factor is usually absent, the hæmorrhagic tendency being here also due to a deficient agglutination of platelets. In hæmophilia a characteristic curve was obtained showing a deficiency also of platelet reaction.—Studies in Blood Coagulation and Hæmophilia. II. Observations on Hæmic Functions in Hæmophilia, by Ronald V. Christie, H. Whitridge Davies, and C. P. Stewart. In hæmophilia the fragility of the red cells was found to be normal, and the serum calcium, plasma non-protein nitrogen, total nitrogen, chlorides, blood cholesterol, and inorganic phosphates were all present in normal amounts. The authors consider that the coagulative defect in hæmophilia is in part due to slow liberation of prothrombin from the platelets, and a slow conversion of prothrombin into thrombin. A deficient chlorine exchange between corpuscles and plasma was also found.—Studies in Blood Coagulation and Hæmophilia. III. The Treatment of Hæmophilia, by Ronald V. Christie and G. Lovell Gulland. Hæmophilia being considered to be due to a deficiency of prothrombin, the introduction of normal prothrombin should produce a temporary amelioration of the condition, which was shown to be the case with blood transfusion. This is an effective means of stopping bleeding from a tooth socket in an hæmophiliac. The most effective local coagulant was found to be cotton-wool soaked in fresh human blood.

INDIAN JOURNAL OF MEDICAL RESEARCH. Vol. XV., No. 1.—E. Muir discusses factors which influence the incidence of leprosy, and, jointly with other workers, contributes a paper on tumour-like growths induced by intraperitoneal inoculation of rat-leprosy.—J. A. Sinton contributes three papers on the anatomy of Indian species of phlebotomus.—R. N. Chopra and others a series of three papers on pharmacological topics.—Charulrata Ray writes on the biochemistry of epidemic dropsy.—J. Cunningham on a simple method of handling squirrels for laboratory purposes, and, together with M. J. Nicholas and B. N. Lahiri, on the value of etherised vaccine for the prophylactic treatment of rabies.—H. W. Acton and J. P. Bose have investigated the susceptibility of rabbits to insulin, and the former, with L. E. Napier, describes post kala-azar dermal leishmaniasis. —Asa C. Chandler contributes further papers on the

[1] Rev. Gén. de Méd. Vet., 1926, xxxv., 417.

prevalence of hookworm and other helminthic infections in India.—L. E. Napier reports upon an analysis of the results of treatment of 61 cases of kala-azar treated with the pentavalent compound of antimony —"von Heyden 693."—R. McCarrison writes upon the experimental production of stone in the bladder, and upon the experimental production of goitre.—C. A. Gill on the forecasting of malaria epidemics.

Reports and Analytical Records.

OSTELIN.

(GLAXO, 56, OSNABURGH-STREET, LONDON, N.W.1.)

Cod-liver oil is far the richest natural source of vitamin D, and is, therefore, the raw material from which such concentrates can most readily be produced. It has been known for some years that the whole of the vitamin D content of cod-liver oil resides in the unsaponifiable non-fatty fraction of the oil, and it is possible to obtain preparations which have a vitamin D activity about 2000 times as great as that of the oil itself. One such preparation, known as ostelin, which has been on the market for about two years, is available in three forms; a glycerin suspension having such concentration that 4 minims are equivalent in therapeutic value to 1 drachm of cod-liver oil; in tablet form, each tablet containing the equivalent of a drachm of the oil and 2 gr. of calcium glycerophosphate; and in combination with malt extract and orange juice, each spoonful of which contains ostelin equivalent to half a spoonful of cod-liver oil together with a like quantity of orange juice. The glycerin suspension can readily be dispensed in mixtures containing calcium salts and other medicaments. Cod-liver oil varies greatly, and it is not possible to prepare an active concentrate from an oil which is itself practically inactive. Tests are carried out in the case of ostelin by employment of the method originally proposed by Zucker, which depends upon an electrometric determination of the hydrogen-ion concentration of the fæces of standard rats. By the aid of this procedure it is possible to evaluate vitamin D content in less than one week. The number of disease conditions which are believed to be due to hypocalcæmia is very great and the phosphorus deficiency which is almost invariably associated with it is no less important. In the course of research work on the effect of ostelin on calcification in experimental rickets in rats, some analytical data were obtained as to the increase both of the calcium content and of the phosphorus of the bones.

	Controls (per cent.).	Experimental (per cent.).	Increase (per cent.).
Lime (CaO)	10·15	19·3	90·0
Phosphorus (P_2O_5) ..	7·8	14·5	86·0

All the animals received Steenbock's basal diet (2965) and the experimental animals in addition 6/10,000 gr. of pure ostelin per diem. Such laboratory results go far to justify the claims made for ostelin in the treatment of nervous disorders, wasting diseases (especially tuberculosis), eczema, and other skin diseases, and in the infantile conditions of rickets, tetany, and spasmophilia in which it acts like a specific.

KIA-ORA PRODUCTS.

(KIA-ORA, LTD., BLACKFRIARS, LONDON.)

In our issue of July 23rd we published an analysis of Kia-Ora Lemon Squash which included a small amount of glycerol. We have since had the opportunity of analysing further samples of this preparation, and we have also made analyses of the same firm's Kia-Ora Orange Squash and also their Orange Crush, analyses of which are appended. In none of these was the presence of glycerol detected, which makes it appear very probable that the amount returned in the first analysis of the Lemon Squash was adventitious, in no way representing the ordinary composition the extract, the more so as the makers assure us th this material is never used by them. Glycerol of course, perfectly harmless physiologically, so t point is not one which has any dietetic significanc

New Inventions.

A NEW PNEUMATIC SPLINT PAD.

IN the treatment of fractures of the leg the box spli in general use is efficient, but we have found advantageous to use a new splint pad. These pa are hollow pneumatic rings, 1½ in. inside diamet strengthened with cord and covered with stockinet which are used in place of the "birds' nests" of wo formerly employed. The latter, often hard and irregul frequently cause skin irritation or ulceration, par cularly behind the heel. The stockinette coveri prevents chafing of the skin from sweat. The ri and the skin may with advantage be powdered extra comfort. Any device which is comfortab efficient, and pressure-relieving should be welcom The new splint pad affords these advantages a maintains the heel in a constant relation to t posterior wooden surface of the splint. The pad d not alter in height after the heel is laid upon therefore, when the fracture is satisfactorily align no change in the relation of the fragments shou occur during the early weeks of union. As with t "birds' nests," several pneumatic pads are requi for each case of fracture treated in the box spli

The pads are made for us by the North Brit Rubber Co., Ltd., Edinburgh.

INDOOR MERLIN CHAIRS FOR ONE-ARM PATIENTS.

IT is common knowledge that the present type Merlin indoor chair, when used by a one-armed m is most laborious, the course being always zigzag a slow, the patient being obliged to use each s alternatively with his one arm. A special Me indoor chair has been designed at my suggestion enable the patient to propel himself entirely from side; it is fitted with two hand-rails, on the work side, in such a manner that both can be gripped w one hand. One rail is fastened direct on to the wh the other rail is connected through a hollow spin to the opposite wheel. When both rails are u (being gently pressed together) the chair is propel directly ahead. Turning movements to right or are accomplished by moving either one or the ot rail, according to the direction required. This insu steady progress in a forward direction and e turning to right or left. This modification is in by several patients at the Star and Garter Ho Richmond, and has proved of very great bene It is a simple and inexpensive device which I s sure will add to the comfort of those who not o cannot walk but have lost the use of one arm.

Messrs. G. H. Dingwall, of 253, Queen's-ro Dalston, E. 8, have converted the ordinary Me indoor chair into the one here described.

EDWARD GOWLLAND, D.S.O., M.B. Lon
Lieut.-Colonel (T.D.), Commandant, Sta and Garter Home.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 3, 1927.

THE TREATMENT OF DIABETES.

THE introduction of insulin by BANTING and BEST has meant an astonishing change in the prognosis of one of the most serious diseases of everyday life. Though the death-rate from diabetes had previously been much diminished by dietetic methods there remained many severe cases, particularly in children and young adults, in which the most careful regulation secured nothing more than postponement of an inevitable catastrophe. To vast numbers of these patients insulin has brought new hope and health; case after case has been rescued from the brink of death, the emaciated have become strong, and children have grown to adult life in safety. The remedy, indeed, appears to be a true example of replacement therapy, since clinically the artificial pancreatic extract takes the place of a deficient internal secretion. In customary therapeutic practice the recognised procedure is to work out a diet which is sufficient for the patient's energy-needs and appetite, but does not raise his blood-sugar above the normal levels or cause glycosuria. Insulin is administered if these requirements cannot be met on a diet compatible with the energy-needs. Hypodermic injections are given daily, or twice daily if need be, in sufficient dosage to prevent glycosuria on a spare but adequate diet. If insulin is needed at all it is needed every day, and although in borderline cases tolerance may improve so much that the drug is no longer required, the majority of patients must continue to take it—though sometimes in diminishing amounts—for many years and possibly for the rest of their lives. This regular hypodermic administration has certain disadvantages. Skill is required, for instance, to keep the syringes and needles clean and to measure the doses accurately, and a certain amount of patience is necessary to put up with the daily pricking of the needle. These are relatively minor objections, and, indeed, it is arguable that hypodermic medication makes for greater safety, since it encourages accuracy in the dosage of a remedy which is so potent as to be a source of danger if any carelessness is allowed. Occasionally, however, a more serious disadvantage of insulin therapy presents itself, and one that is not, perhaps, fully appreciated. Each meal increases the sugar-content of the blood, and when this rise is very large an injection of insulin must be given with the meal in order to counteract it. This counter-action, to be successful, implies an absorption of insulin into the blood at a rate closely parallel to the absorption of sugar from the intestine, and unfortunately it sometimes happens in very severe cases of diabetes that the unusually large dose of insulin is absorbed more quickly than is desirable and produces temporary hypoglycæmia, this in turn being followed by hyperglycæmia with glycosuria when, some hours later, the sugar from the meal reaches the blood in full concentration. Such cases, although rare, present great difficulties, and the need has long been felt for a drug which can be administered by mouth, and so absorbed simultaneously with the food.

Attempts to secure a form of insulin which acts after oral administration having so far proved ineffective, there has been much experiment directed towards the discovery of some other compound with similar actions. On one of these, produced by Prof. E. FRANK of Breslau, we are able to publish a preliminary report. It has been known now for some time that certain guanidine compounds will produce a fall of blood-sugar when given by mouth, but the general symptoms of poisoning which accompany the phenomenon have made such compounds useless for therapeutic purposes. Experimenting with homologues of guanidine, Prof. FRANK has prepared a substance which he calls synthalin [1] and which is a diguanidyl derivative of a long chain aliphatic hydrocarbon. Its chemical formula is for the moment unrevealed publicly. It has been on trial in many German clinics for a considerable period and has also been available to a lesser extent in other countries. In view of the fact that its exact constitution is not divulged, the remedy has not been generally issued to the profession in Great Britain, but the Medical Research Council, having received confidential communication of the formula, were able some months ago to accept supplies of the substance, and with the support of Prof. FRANK invited a number of clinicians to give it a clinical test. Accounts of their investigations will be found in the Council's report published in our present issue, and it will be seen that tests have been made under carefully controlled conditions at the majority of the London hospitals, and at Bristol, Manchester, and Edinburgh. Published reports in Germany have been somewhat confusing, certain authorities apparently stating that synthalin is a satisfactory substitute for insulin, whilst others have been cautious or even sceptical in their comment. The individual statements in the British report reveal a rather similar lack of unanimity, but careful reading of the whole allows us to reach certain definite conclusions. Some of the observers, for example, have in very restricted series of cases seen no reduction in glycosuria following the administration of synthalin, but the majority have been able to establish that the new product definitely diminishes the excretion of sugar, when it is given in sufficient quantity. The effect on the blood-sugar is more doubtful, and, indeed, it is open to question whether an effectual reduction is ever brought about by the administration of synthalin in non-toxic doses. The total number of cases studied by each investigator has been so small that most of them are reluctant to draw conclusions, and for the same reason the Medical Research Council has made no attempt at this stage to correlate or summarise the findings of the different workers. Our analysis, which follows, is made with appreciation of the stress that should, or should not, be laid upon minute groups of figures. Taken as a whole it is not encouraging. It is possible to extract fairly full details of about 50 cases in which the new compound has been employed and these may be divided into two groups, the first

[1] THE LANCET, 1927, i., 35, 1168, and 1266.

consisting of 20 patients—most of them middle-aged or elderly subjects—who were treated with synthalin alone. These were all on a controlled diet, and were regarded as definitely diabetic, most of them having considerable glycosuria. In eight of them the sugar in the urine was reduced in amount; in eight others the treatment was stopped on account of toxic symptoms; in three the synthalin had no apparent effect, whilst the twentieth patient never had glycosuria at all. When it is further noted that in three of the moderately successful cases glycosuria was completely abolished by further regulation of the diet, without administration of synthalin, it becomes apparent that the results obtained with this drug have been in general disappointing. The second group comprises 32 cases in which insulin was being administered, and in which synthalin, in varying doses, was given in an endeavour to replace hypodermic by oral medication. In 11 of these it was found that the dose of insulin could be reduced when synthalin was given; in 11 others there was no effect at all; and in six the effect was very doubtful. Four cases remain; in two of them treatment with synthalin was abandoned because of toxic symptoms; in one the dose of insulin could be reduced but glycosuria was always present, whilst in one case only, among the 32, does synthalin appear to have been used successfully to replace insulin. A further word must be said concerning the toxic symptoms, which are chiefly gastro-intestinal, such as anorexia, vomiting, and diarrhœa. They occur fairly frequently but with careful regulation of dosage are seldom alarming. In one or two instances the symptoms have been suggestive of hepatitis, but in the majority they have been merely those of intestinal irritation. It must, however, be noted (as one physician emphasises in his report) that anorexia and diarrhœa will often interfere with absorption of food and thus tend to reduce glycosuria in diabetic subjects. Sodium di-hydrocholate, which has been introduced by a German firm under the name of decholin, is said to be useful for the prevention of these toxic symptoms, but unfortunately supplies of this substance were not available in this country until most of the trials under the Medical Research Council's scheme had been practically completed. At the same time there were few among the reported cases in which the symptoms were such as to call for the use of decholin.

Examination of the German literature suggests that synthalin has its greatest value in the treatment of elderly diabetics, among whom, all authorities admit, the disease is relatively mild. No remedy can take the place of insulin, really unless it has a powerful effect on the severe diabetes of children and young adults. Whereas the recorded results obtained with synthalin in this country are, on the whole, disappointing, the effects of insulin are well known to be very satisfactory, though they call for intelligence and a certain amount of self-sacrifice on the part of the patient. It would, therefore, be most unfortunate if sufferers from diabetes were generally led to believe that synthalin offers them a less difficult road to health. It cannot be too strongly stated, moreover, that the successful treatment of diabetes necessitates careful dieting, and that this necessity is not obviated by using any known therapeutic substance. British patients are usually abstemious as regards their food, and the safety of the diabetic depends upon moderation. It would be a real calamity if enthusiasm for any new remedy were to cause any relaxation of the sound dietetic rules which have been so successful in recent years in the treatment of this disease.

TELEGRAPHISTS' CRAMP.

THE report of the Industrial Fatigue Research Board [1] on telegraphists' cramp, which has just been issued, indicates the modern approach to the problem of this occupational neurosis. It may at the same time throw light on the development of neuroses in general, the mention of which used until recently to call up little more than an indefinite picture of nerve cells misbehaving in some mysterious way so as to produce symptoms conforming to no known pathology. In a report published in 1911 earlier investigators made frequent use of such phrases as "nervous instability," "temperamental factors," "highly strung disposition," and the like, with no attempt to indicate how the conditions were to be detected, or in what way they could influence the onset of cramp. In the investigations now recorded, cramp subjects and a series of non-cramp controls were put through tests involving the use of the ergograph, the pursuit-meter, the McDougall-Schuster dotting machine, and the piezograph—the last-named being a telegraph key attached to an instrument recording the pressure exercised in sending messages. The results of the tests, which were carried out by Miss MAY SMITH and Mr. ERIC FARMER, showed great variability; the cramp subjects were on the whole definitely worse than the non-cramp, yet in some cramp subjects the results were better than in some controls. This anomaly was in keeping with the confusing diversity of the symptoms; some subjects, for example, suffered from a general disability to use the arm even for gross actions such as digging, whilst in others the disability affected only the sending of particular, but not all, combinations of dots and dashes. It is difficult to imagine this diversity as being in relation to any specific localisation of deranged function, but a further investigation, carried out by Dr. MILLAIS CULPIN, into the emotional state of the subjects as likely to be reflected in modes of behaviour, offers a possible explanation of some of the anomalies.

This investigation showed that 31 of the 41 cramp cases suffered from symptoms that would lead, quite apart from the cramp, to a diagnosis of a minor mental disturbance (psychoneurosis) characterised by anxiety, obsessions, or hysteria. One subject had an organic lesion, but nine had no discoverable symptoms apart from cramp, and six of these showed no disability as measured by the tests. The common picture of a cramp case is a combination of psychoneurotic symptoms with muscular inefficiency. Of 46 non-cramp subjects 15 had psychoneurotic symptoms of varying degree. The next step was an examination of 100 young learners in the school of telegraphy to find whether any were akin to the cramp group, and the rather startling result emerged that 19 showed definite psychoneurotic tendencies, six of them in such a severe form as to admit of classification in one or other of the recognised groups of psychoneurosis. The tests, particularly the dotting test, again showed a strong tendency in the psychoneurotics to fall below the average, and 11 per cent. of the whole group approximated to the common cramp picture. Lastly, other groups of clerical workers were similarly examined, and again it was found that roughly 20 per cent. had symptoms indicative of liability to breakdown, though their symptoms could not find direct expression in their work. The investigators point out that telegraphy requires from the operator certain qualities that are more temperamental than intellectual, and they believe that no allied

[1] H.M. Stationery Office. 1s. 6d.

occupation makes such exacting demands. Specific psychoneurotic tendencies are stimulated by the inevitable conditions of the work and, although not expressly stated in the report, the conclusion seems to be justified that cramp most often depends upon a pre-existing psychoneurosis which is exacerbated by the stresses peculiar to telegraphy and then manifests itself by a symptom—if the vagaries of cramp can be called a symptom—which takes as its pivot the manipulations upon which the stresses depend. It follows that young people already showing psychoneurotic symptoms or muscular inefficiency, and especially the two in combination, should not be advised to take up telegraphy, and that attention given to the emotional state of the patient when cramp first appears might offer a means of preventing its development.

In an appendix to the report Prof. M. GREENWOOD shows that a statistical comparison between the investigators' results and the judgment of the individual learner's ability, as formed by teachers in the school, indicates that the methods of investigation—both the tests and the temperamental inquiry—explore qualities related to that ability. The pursuit of the investigation outside the sphere of telegraphy has revealed an unsuspected prevalence of psychoneurotic tendencies among the general population, even among the youthful members; this work is along novel lines, and Dr. CULPIN'S figures, though to some extent confirmed by their correlation with the objective tests, must largely depend upon personal judgment. In view of the part played by psychoneurotic disabilities in modern life, this part of the investigation is important enough to call for confirmation by independent observers.

THE DESCENT OF MAN.

WE are all too apt to overlook the simplest and most fundamental conceptions on which our thinking lives are based. We cannot be reminded of these too often nor can they be restated too frequently. Sir Arthur Keith's presidential address to the British Association at Leeds, which we print on another page of this issue, is of real and immediate moment to medicine and hygiene, though he tells a tale and reaches a conclusion which are familiar enough. Putting aside the difficult questions of the meaning and mechanism of evolution, he shows that all the evidence which has accumulated in the last 60 years has done nothing but strengthen Darwin's proposition that man is descended from the lower animals. It is a truth—or if anyone prefer the phrase, a working hypothesis—which we cannot drive too firmly into our minds, for there is still much to be done in working out its implications for human life. To find the remains of a branchial cleft in a man's neck is to have a pleasing contact with a noble conception. And as man's body has come from animal's flesh, so it is hardly possible to deny that all that governs and inspires his functions is correlated with the same source. We do not sufficiently reflect that Darwin's argument about the history of man's form is equally applicable to the history of his function; we get indeed more useful help from evolution in understanding what man does than in appreciating his anatomy. As a historical tool, therefore, the idea is indispensable and it may be expected to yield at least as much in the future as it has in the past. But a real belief in evolution implies more than this interest in what has gone by. If progressive change in the constitutions of animals has happened in the past, we have no reason to doubt that it is happening now and will go on happening in the future. What man will come to, no one can tell. But a belief in the Descent of Man is the first and necessary component of that lively faith in the possibilities of human amelioration without which no serious attempts at perfection can be long maintained.

Annotations.

"Ne quid nimis."

SURGERY AND THE DIAPHRAGM.

THE mechanical aspect of respiration, and particularly the physiology of the diaphragm, is still imperfectly understood in spite of much investigation, and even less can its activities be controlled. The importance of the subject may be judged by considering that post-operative basal pneumonia, massive collapse of the lung, and pulmonary embolism have all been attributed to inadequate or abnormal action of the diaphragm. Our ignorance is revealed by the conflicting theories as to the cause of massive collapse and the uncertain results that follow evulsion of the phrenic nerve—a procedure that theoretically should produce a massive collapse with some degree of precision. The question has mainly been studied in connexion with post-operative complications, and in America estimations of vital capacity have been used to gauge the effect on respiration of various types of operation. Using this method Dr. J. R. Head [1] found that operations on the upper abdomen reduce the vital capacity most of all—in some cases by 70 per cent. of the pre-operative figure. On the other hand, in chest cases a low pre-operative capacity is often surprisingly little affected even after an extensive resection of ribs. The probable explanation is that in such cases the diaphragm is in no way restricted and can to a great extent take over the work of the intercostal muscles when the ribs are constricted by a tight binder. Dr. Head is probably right in considering that after abdominal operations the reduction in vital capacity is mainly, if not entirely, due to deficient expansion at the bases of the lungs, and that his figures are in some degree an index to the extent of this deficiency. Further, upper abdominal operations are more liable than any other type to be followed by pulmonary complications, so there appears to be some connexion between such a liability and a large post-operative fall in vital capacity. He clearly realises the drawbacks of the method, for he states that vital capacity, "being a maximum gross reading, fails to indicate the state of quiet breathing and the relative aeration of different lung areas." But this is the very heart of the problem, for it is on precisely these two factors that the liability to pulmonary complications depends, so it is unlikely that this line of investigation will prove of much value. The part of the respiratory mechanism at fault must be the lower ribs and diaphragm. The former are constricted by a binder and cannot expand; the latter is inhibited. Opinions differ as to whether this inhibition is due to voluntary, reflex, or postural causes, and further research is needed on this point. The physiology of the diaphragm has been especially studied by Sir Charlton Briscoe; and the clinical observations and methods of diaphragmatic education described in his recent Lumleian lectures [2] are of great interest and importance in this connexion. Till a method is devised to keep the diaphragm active in the presence of an abdominal wound it seems that basal pneumonia, massive collapse, and possibly pulmonary embolism will continue to beset the practice of surgery.

ERYTHEMA NODOSUM AND TUBERCULOSIS.

THE growing tendency to regard erythema nodosum as a manifestation of tuberculosis, to which we have alluded quite recently,[1] finds expression in a communication[2] by Prof. Rudolf Massini, of Basel. During the past ten years 29 cases of erythema nodosum have been observed there in the Bürgerspital, and an analysis of this material shows how frequent is the coincidence of the two diseases. Among the 29 patients there were three suffering from definite pulmonary tuberculosis (it broke in one of these cases three years after the appearance of the erythema nodosum), six suffering from pleurisy with effusion, one each from peritonitis, miliary tuberculosis and tuberculosis of the lymphatic glands, four from a subfebrile temperature suggestive of tuberculosis, one showed X ray signs of healed pulmonary tuberculosis, one suffered from tuberculosis of the bones, and one from Bazin's erythema induratum and Boeck's sarcoid. Altogether a formidable list of tuberculous manifestations. They were more common as sequels to, than as concomitants of, the erythema nodosum, and it was significant that these outbreaks of tuberculosis assumed most often the exudative progressive form. What was curious in the light of the opinion that erythema nodosum is simply a manifestation of tuberculosis was the unequal sex incidence in Prof. Massini's material; there were only three males to 26 females. Most of his patients were under 27, and the time of year most favoured was the spring. That the disease should show a certain seasonal incidence does not, in his opinion, necessarily invalidate the supposition that it is of a tuberculous character, for he points out that tuberculous meningitis also shows a preference for the spring. There was little in his material to correlate erythema nodosum with rheumatism, and only in three cases was there a definite history of typical, acute, rheumatic fever. He considers three possible relationships between the disease and tuberculosis: (1) It is an exanthematic rheumatic disease sui generis, the outbreak of which is favoured by tuberculosis, particularly by its acute forms. (2) It is a disease sui generis which favours the subsequent outbreak of tuberculosis. (3) It is itself a form of tuberculosis—an acute exudative form. While the exact nature of the relationship between erythema nodosum and tuberculosis still remains to be defined, enough is already known to guide our conduct in cases of this skin disease; the prospect of the development of a grave tuberculous disease in the near future is an indication for taking those prophylactic measures which our knowledge of tuberculosis has put into our hands.

PROTECTION IN RADIOLOGICAL WORK.

THE third revised report of the X Ray and Radium Protection Committee has recently been published, and it seems clear that its sphere of usefulness is being widened. Formed in 1921 under the chairmanship of Sir Humphry Rolleston, the committee has been enlarged and strengthened by the coöption of Dr. A. E. Barclay, Mr. C. Thurstan Holland, and Dr. Woodburn Morison, and its recommendations represent in very complete and practical form the considered opinion of British radiologists. The original suggestions have been very largely adopted, and it is interesting to note that where the same questions have been considered in other countries the proposals for protection are even more stringent than those originally put forward by the Committee. There is, of course, one outstanding difficulty in the application of such proposals to X ray work—namely, that they make the apparatus much more unwieldy; in some cases, indeed, it has been urged that with heavily protected apparatus it is impossible to do the same kind of work as can be done with appliances which are only slightly protected. But there is little doubt that the ingenuity of the designer will in time get over this difficulty, and allow complete freedom of use and action with apparatus bearing ample protection. An important addition to the report is a section on the precautions necessary in ultra-violet therapy. One of the most serious dangers here is the damaging effects which the rays have upon the eye, and insistence is laid upon the use of glasses of proved opacity to rays shorter than 3800 A.U. We have every reason for believing that the recommendations of this Committee on the subject of protection are gaining general acceptance by radiologists. The governing bodies of institutions where a large amount of X ray work is undertaken may in their turn feel assured that if the general lines of these reports are followed no harm is likely to be done either to patient or operator. The Committee, however, claims no infallibility, and expressly mentions at the end of the report that it will welcome suggestions or information which would lend to improve the schemes of protection which are outlined. Copies of the report may be had from the Hon. Secretaries of the Protection Committee at the British Institute of Radiology, 32, Welbeck-street, London, W., or from the Director of the National Physical Laboratory, Teddington, Middlesex.

COD-LIVER OIL AND MALT.

IN the latest annual report of the medical officer of health for Glasgow there is a section dealing with the Sale of Food and Drugs Act, and this section records an inquiry into the composition of cod-liver oil emulsions and mixtures of cod-liver oil and malt extract. In a former year a sample of malt extract and oil was found to contain only 2·82 per cent. of oil, and it was believed that this was not exceptional. In six samples of emulsion taken during 1926 the percentage of cod-liver oil varied from 23·2 to 51·05 per cent. Among the samples of extract of malt and cod-liver oil the percentage of cod-liver oil by weight varied from 2·94 to 12·51 per cent. If the malt extract is to be regarded chiefly as a vehicle, it certainly seems ludicrous that it should be necessary to consume over 30 teaspoonfuls of the mixture in order to get one teaspoonful of oil. Cod-liver oil is so much used now that the matter becomes important, and there will be general agreement with Dr. Macgregor's suggestion that the approximate percentage of oil should be declared on the label in the case of these preparations. This is only one of a number of interesting subjects dealt with in the report, a review of which appears on p. 524.

THE N.S.P.C.C.

IT commonly happens that a parent brings his child to hospital and then refuses to allow some necessary form of treatment. The refusal is sometimes comprehensible, but is nevertheless exasperating to the out-patient medical officer. The impasse appears complete, and just when it seems possible that parental obstinacy will cost the child the sight of an eye (for example), someone thinks of the National Society for the Prevention of Cruelty to Children; an urgent call for help is sent, and, as often as not, the inspector's arguments are effective. Some supporters of this Society have questioned the propriety of establishing and developing the Medical Branch, but it is becoming more and more obvious that this extension of the Society's activities is wholly consistent with its main object—"that every child in the land shall have an endurable life." The report for 1926–27 gives many indications of the useful coöperative work which the N.S.P.C.C. is doing. For instance, by means of the ambulances which the Society owns, and by arrangements made with hospital authorities, it has been found possible to overcome some of the difficulties of transporting children for treatment; as the report points out, the order "Take your child to hospital" is sometimes much easier to give than to obey. Cases are referred to the London medical branch of the Society by the London County Council, by hospitals,

by welfare centres, and by other bodies. In the year under review there were 611 new cases affecting 725 children, which gives some indication of the medical work entailed. Advice as to treatment is now frequently asked for by parents, and a large part of the inspector's work is to see that treatment is carried out. In the large majority of cases defective teeth and defective vision are the disabilities needing medical intervention, but the Society is also able to help those who are crippled in other ways, not only by securing admission to hospitals, but also by giving assistance in getting surgical appliances. Dr. L. D. Saunders, the medical officer of the Society, definitely states that opposition is becoming rarer, and if progress is maintained there will surely come a time when public opinion is so enlightened that no child's life will be rendered unendurable by a remediable physical defect.

CLINICAL PERIMETRY.

To the older generation of ophthalmologists the estimation of the field of vision appeared to be a comparatively simple procedure. It meant the definition of the field in ordinary daylight for white and for coloured objects in its periphery, the detection of any obvious enlargement of the blind spot, and of any absolute scotoma, whether central, paracentral, or peripheral. So much can be accomplished by the older methods and suffices for clinical purposes in many cases of advanced glaucoma, optic atrophy, partial cutting off of the vascular supply, and various well-defined cases of hemianopia. The conception of the visual field which modern perimetry suggests is not so simple. It differs from the older conception in that it is not merely qualitative but also quantitative —i.e., it takes into account not only the fact that there is or is not any visual acuity at all in any particular spot of the field, but also the degree of the acuity at that particular spot. It is this quantitative conception of the field with which Dr. Traquair has recently been concerned.[1] He compares it to an island of vision surrounded by a sea of blindness.

"The coast-line is somewhat ovoid in shape, and rises steeply, so that the island is surrounded by cliffs, vertical on one side, sharply sloping on the other. Above the cliffs is a sloping plateau which rises more rapidly again towards the somewhat eccentrically situated summit. This is crowned by a sharp pinnacle whose sides curve steeply upwards from a narrow base. To one side of this point is a pit (the blind spot) with sides almost vertical at first, but soon becoming perpendicular, which extends down to the level of the surrounding sea . . . If we choose to exercise our imagination still further, and picture to ourselves this island under abnormal conditions, we must think of it as distorted or partially destroyed by subsidence. Depressions of every variety may occur on its surface, of all shapes, sizes, and depths, with straight, curved, or irregular margins, with sloping or steep sides, isolated or extending to the shore or to the pit, or partly or wholly involving the central pinnacle."

We make no apology for the length of the foregoing quotation, for it illuminates a subject which is of growing importance to both the ophthalmic surgeon and the neurologist, who will look in vain for such a light on it in even the most up-to-date of the general ophthalmological text-books. Bjerrum's screen, it is true, is always mentioned in connexion with the detection of central scotomata. But the special function of this or any other form of scotometer for detecting relative defects in the field by means of using small test objects at distances greater than 33 cm. (that of the ordinary perimeter), is seldom explained, and nowhere so well as in this book. The chapters in Part I. deal with the normal field of vision, perimetric instruments, methods of examination, and the physiology of the visual field in relation to clinical perimetry. Part II. is entitled Applied Perimetry, and deals with the pathological field, and the interpretation of changes in the visual fields; also with the relation of these changes to affections of the choroid and retina, to glaucoma, to affections of the optic nerve, to the chiasma and the suprachiasmal pathway, and finally to functional conditions such as hysteria. Figures as to the exact limits of the normal field, according to different observers, are relegated to an appendix, and a bibliography gives references to over 300 papers published in European and American journals dealing with various aspects of the subject. The diagrams are an essential aid to the reader, and the print is luxurious. The work should prove invaluable alike to the ophthalmic surgeon and to the neurologist.

[1] An Introduction to Clinical Perimetry, by H. M. Traquair, M.D., F.R.C.S. Edin., Assistant Ophthalmic Surgeon, Royal Infirmary, Edinburgh. With 164 illustrations and a coloured plate. London: Henry Kimpton. 1927. Pp. 264. 30s.

DANTE AND RABELAIS.

AT the recent Edinburgh meeting of the Royal Medico-Psychological Association Dr. Hamilton Marr gave an interesting presidential address entitled Dante and Rabelais: An account of two Mediæval Physicians, with a Summary of their Philosophy. Rabelais undoubtedly was a qualified physician and practised his profession in the city of Lyons, but as Dr. Marr pointed out, it is news to most of us that Dante was a medical man. He certainly enrolled himself in 1295 or 1296, in the Guild of Physicians and Apothecaries, but that was in order to qualify for participation in the government of Florence, and it is probable that he knew no more medicine than a member of the Mercers or the Cutlers Company to-day knows of mercery or cutlery; in the roll of the Guild of Physicians and Apothecaries Dante is described as *poeta*, although as a universal scholar Dante shows a knowledge of medical matters in his works. Dante's works, especially the "Divina Commedia," are a summary of mediæval philosophy and theology, expressed in exquisite language and full of the love of nature. Just as in the Iliad fire is the dominating element, so in the "Divina Commedia" light is. Rabelais, who lived some 300 years later than Dante, was a man of a very different type; but if we eliminate his coarseness, which is in no way necessary to his philosophy, what a treasury of satire and sound good sense remains. Born in different ages, varying in their outlook on life, both Dante and Rabelais set forth three great principles: to live in this world as a preparation for the next, to love one's neighbour as one's self, and to reverence knowledge. The work of to-day is so arduous, and so much modern knowledge has to be acquired, that medical men owe a debt of gratitude to Dr. Marr for having so pleasantly set forth the advice of two old-time scholars. His address will no doubt appear in a forthcoming issue of the *Journal of Mental Science*.

OPIUM-EATING IN INDIA.

THE extent to which any particular form of drug addiction is undermining the health and efficiency of a nation is difficult to estimate, especially when the drug in question has wide medicinal value. Statistical figures of consumption, although they may show the general trend towards increase or decrease, do not reveal details and are notoriously fallible. In India, for instance, where opium has been used as a household remedy for generations, there is great difference of opinion about the extent of its abuse, and this has led Dr. R. N. Chopra and Dr. K. S. Grewal [1] to begin a detailed study of the opium habit in the Sikh community in Calcutta, amongst whom it is prevalent. The majority of these Sikhs are engaged as taxi-drivers, watchmen, or artisans. They take their opium by the mouth, as is usual in India, where opium smoking is rare. One hundred cases were examined in detail, and analysis of these showed that by far the commonest cause of opium taking (58 cases) was the association with and example of addicts. Pain and disease was the next cause (30 cases), but in only four of these was the drug first used on the advice of a physician. Of the occupations considered, taxi-drivers head the

[1] Indian Journal of Medical Research, July, 1927.

list, probably because they are comparatively well off, and have plenty of time for rest and social intercourse between fares. In 81 cases the habit was acquired below the age of 35, and, once started, it tended to continue for many years. Sixty-five of the addicts declared that opium-eating did them harm; they wished to give it up but were afraid to do so because of the symptoms which develop on withdrawal of the drug. Heredity did not appear to be an important predisposing cause. In this series of 100 addicts, 34 took from 10 to 20 gr. of opium a day, 25 per cent. took more than 20 gr. a day, and a number of the latter took over 50 gr. The larger doses were taken by the younger men. Individual study showed that the habit decreases working capacity, whilst the rapid onset of withdrawal symptoms quickly causes slavery to the drug. It is worth noting that all the addicts examined were at work. This probably means that the later and more disastrous consequences of the habit are masked, for these would be found among men who were no longer fit for employment.

THE ANOPHELINE MOSQUITO.

IT is now nearly 30 years since Ross in India first demonstrated the presence of the parasites of human malaria in the gut of "dapple-winged" mosquitoes. Since then a large amount of research has been carried out in various parts of the world regarding the part played by anophelines in the dissemination of the disease. At first it was thought that all anopheline mosquitoes were equally concerned in the transmission of malaria, but research by Stephens, Christophers, James, and others effectually demonstrated that certain species were far more efficient malaria-carriers than others. In considering the part played by different species, it has to be remembered that many factors may affect the results of observation. Amongst these may be mentioned the time of the year at which the investigation is carried out, and whether or not malaria is rife at the time. As is pointed out by Swellengrebel, Schüffner, and de Graaf, several questions must be answered in assessing the capabilities of any particular species. Does the species occur in great numbers? Is it capable of allowing the parasites of malaria to complete their development? Does it habitually feed on human blood, not only in captivity, but also in nature? Does it feed in the jungle, or does it regularly visit man in or near his dwelling-places? In an Indian medical research memoir [1] of 117 pages Major G. Covell, of the Central Malaria Research Bureau, Kasauli, has now summarised all the available information on these subjects, arranging the known species of anopheles in alphabetical order. He has considered the distribution, breeding-places, habits, relation to malaria, and experimental infections of anophelines, and in so doing has conferred a very considerable boon on his fellow-workers not only in India but throughout the tropical world. The report includes a very complete bibliography as well as an index.

TYPES OF STREPTOCOCCI IN SCARLET FEVER.

Dr. F. Griffith, of the Ministry of Health, has found that hæmolytic streptococci isolated from cases of scarlet fever fall into three main serological groups (Types 1, 2, 3), while a large heterogeneous group of organisms—roughly 50 per cent. of the whole—which seem to possess individual antigenic properties are designated Type 4. Of these groups Type 2 is the most sharply defined, and is found only in association with scarlet fever, while Types 1 and 3 show relationship with hæmolytic streptococci from non-scarlatinal sources, such as puerperal fever and sore-throat. Similar results have also been obtained by G. R. James and J. Smith, and an attempt has now been made by Dr. William Gunn [1] to correlate the type of streptococcus found in scarlet fever with the clinical findings. One hundred patients with scarlet fever were investigated, and streptococci were isolated from 93 of them. In two cases the organisms were of Type 1, in 34 cases of Type 2, and in 17 cases of Type 3, whilst in the remaining 40 they were either of Type 4 or unclassified. The proportion of types was not dependent on any age-groups. No definite conclusions could be drawn about streptococci of Type 1 as only two cases occurred in the series; Type 2 was associated with the most typical and severe forms of the disease; Type 3 with those which were less severe; and Type 4 appeared to cause only a mild attack. The complications were most severe when Type 2 organisms were found, and were less numerous and severe in Types 3 and 4. Infection by the unclassified strains clinically resembled infection by Type 3. There were four instances of scarlet fever occurring in two members of the same family, and in each case the type of streptococcus isolated from different members of the family was the same (Type 2 three times and Type 3 once). The differences in type of the scarlatinal streptococci may explain the different results obtained with the same batch of scarlatinal antiserum in cases apparently similar from a clinical standpoint, and may also explain why some cases give anomalous results to the Dick and Schultz-Charlton tests. It will be necessary to consider the risk that a patient with mild Type 4 infection may be attacked whilst in hospital by a virulent Type 2 streptococcus; it has often been observed that when hospital beds are close together the proportion of cases developing scarlatinal complications may become larger. Though the importance of recognising the various types of scarlatinal streptococci has not been fully determined, it is obvious that ætiology of scarlet fever is not quite as simple as was thought at first.

WE offer our congratulations to Mr. Priestley Smith on receiving the Lucian Howe medal of the American Ophthalmological Society. This medal has been awarded only three times previously, the recipients being Dr. Kohle, of Vienna, who first used cocaine in ophthalmic surgery; Prof. Fuchs, of Vienna; and Dr. Edward Jackson, editor of the *American Journal of Ophthalmology*. Mr. Priestley Smith was personally visited, on behalf of the Society, by Dr. W. H. Wilder, who took the opportunity of seeing the apparatus which Mr. Smith is using in his investigation of the circulation of the eye.

WE are asked to remind readers that the next session of the *Journées Médicales*, organised by a committee of the *Revue Pratique des Maladies des Pays Chauds*, will take place from Dec. 15th to 24th, 1927, in Cairo. All communications should be addressed to M. Zeitoun, Secrétaire-Général, 32, Rue Gay-Lussac, Paris (V.). The organisation has received the support of numerous influential Egyptians both as patrons and as active collaborators. The Committee have under consideration the proposition recently made by the Egyptian Government to make a session of the *Journées Médicales* coincide with the centenary of the Kasr-el-Aini Hospital in December, 1928, and we learn that there is every intention to establish a close relationship between the two movements.

[1] Memoir No. 7 (Supplementary Series to the Indian Journal of Medical Research). A critical review of the data recorded regarding the transmission of malaria by the different species of anopheles; with notes on distribution, habits, and breeding-places. By Major G. Covell, M.D., I.M.S. Published for the Indian Research Fund Association by Thacker, Spink, and Co., Calcutta.

LEGACY TO THE PASTEUR INSTITUTE.—The death has occurred at his villa at San Remo of Dr. Réné Marius Appert, of Paris, aged 65, who has bequeathed the residue of his estate to the Pasteur Institute, Paris. The value of the legacy is expected to approximate to £160,000.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXXIX.

THE TREATMENT OF G.P.I. (PARESIS; DEMENTIA PARALYTICA).

I. THE RECENT CASE.[1]

PARESIS has for long been regarded as a hopeless condition in which treatment was of no avail. This is not now an accurate view. Life can be prolonged and remissions encouraged by prompt treatment and proper care.

Early Diagnosis.

Early cases offer the most favourable prognosis. Character changes in early middle life, or later, should provoke a minute search for the well-known physical signs of general paralysis on the part of the practitioner. If there is any doubt specimens of the blood and cerebro-spinal fluid should be obtained forthwith, so that any uncertainty can be quickly resolved. The refinement and accuracy of modern methods of diagnosis should ensure the recognition of paresis at a very early stage. Advanced cases may improve under treatment, but psychical defect nearly always remains.

Malaria Therapy.

The malarial treatment offers new hope in the treatment of paresis. It is the natural result of the almost despairing use of substances which have had some unknown stimulating effect on tissue resistance, indicated by a sharp leucocytosis and accompanied by pyrexia. Injections of such substances as nucleinic acid, sodium nucleinate, phlogetan, and lecithin have been followed by improvements. Sera have also been used, and vaccines prepared from a variety of organisms have been tried.

The treatment of paresis by inducing an attack of benign tertian malaria gives results which hitherto have never been attained. Not every case of paresis is fit for treatment by malaria, and several considerations must be weighed carefully before it is decided upon, but the method can be advised for every suitable case. An important factor is the age of the patient. The older he is the less satisfactory the result, and the greater the risk of a fatal issue. For a patient older than 45 the treatment entails increasing risks, and results may be poor. The response seems to be best in the classical elated or manic patient. The depressed paretic, the tabo-paretic, and the slowly dementing forms of the disease give less satisfactory results, though exceptions do occur. Renal disease, the presence of jaundice, cardiovascular disease, and marked anæmia increase the risk of malarial therapy and may even contra-indicate its use. A careful examination and frank discussion with the family should precede treatment when patients are suffering from conditions which will add to the dangers of the pyrexial period.

Technique.

The treatment consists in infecting the patient with benign tertian malaria, and allowing the malaria to continue unchecked until 10 to 14 rigors have occurred, when the fever is controlled by the administration of quinine. The best means of producing infection is to take 3 c.cm. of blood from a patient already under treatment, preferably during a febrile attack, and injecting it subcutaneously in the subscapular region of the recipient. After an interval, which varies from 6 to 21 days, the rigors commence and should be allowed to continue as long as the patient can safely tolerate them. Another method is the use of suitable infected mosquitoes, which are procurable with the generous assistance of the Ministry of Health. The mosquitoes are brought to the patient in glass containers which are applied to the skin, and are allowed to bite freely. In my opinion, the malaria produced by mosquito bite is less easy to control by quinine than that produced by infected blood, and relapses of the fever more frequent. During the pyrexia confusion, delirium, and hallucinations are common, and wild excitement may occur. On the whole the patients are fairly tractable. The treatment will necessarily confine the patient to bed, though he may be allowed up between the first two or three rigors. The pyrexia varies, but temperatures of 104° to 106° F. are common. The fever may be tertian, with rigors on alternate days, but is often double tertian, the paroxysms taking place daily.

Regular examinations of the urine should be made. Albumin is sure to appear, but need not cause alarm unless it becomes large in amount. Pronounced albuminuria, the appearance of jaundice or marked collapse are indications for arresting the course of the malaria, but it must be remembered that the best results follow 10 to 14 rigors. No treatment must be allowed during the rigors save sponging when the temperature rises to 105° or more.

The administration of quinine by the mouth arrests the malaria in a most effective manner. Quinine sulphate, or hydrochloride, gr. x. t.d.s. for three days, produces a rapid subsidence of the fever, and the parasites disappear from the blood. The quinine is even more effective if given intramuscularly, and when there is an urgent need to control the pyrexia it may be given intravenously. The patient will have lost weight, may be weak and anæmic, but as convalescence becomes established the mental condition should improve, and may continue to improve for three or four months after the cessation of the treatment. During this period novarsenobillon or sulfarsenol should be administered intravenously. It is well not to begin with too large a dose, and to increase the doses gradually. The malarial treatment may be carried out at home, in a nursing home, or hospital. The room of the patient is best rendered mosquito-proof by framing the windows and door with fine net. A frame may be made also for the bed, which can with advantage be protected.

The patient should be instructed to return for a course of treatment by arsenical compounds every six months during the remission of his symptoms. Lumbar puncture is useful in giving laboratory information as to the result of the treatment. The Wassermann reaction remains positive, but there should be a pronounced fall in the lymphocyte count and a diminution in the globulin content.

Other Methods.

Trial is being made of a method for inserting salvarsanised serum into close contact with the surface of the brain by performing cisternal puncture. When convalescence after the malaria is established a dose of N.A.B. is given, and after 30 minutes some ounces of blood are withdrawn, from which the serum is extracted. The following day, under a general anæsthetic, a needle is inserted into the cisterna magna, and the serum introduced, first withdrawing a similar quantity of cerebro-spinal fluid. Six injections are given at weekly intervals and very marked improvement has been recorded. Tryparsamide, a sodium salt of N-phenylglycineamide-p-arsonic acid, is also being used for the treatment of paresis. It is one of the substances which apparently passes the choroid plexus, and though there are definite risks associated with its use, it may be advised where other methods have failed. It is best given intravenously in doses of from 1 to 3 g. dissolved in 10 c.cm. of sterile distilled water. Not less than eight days should intervene between the injections, and eight injections complete the average course. Ocular disturbances are the chief risk. They may be temporary, but complete and permanent blindness has resulted in some cases from the use of tryparsamide.

[1] An article by Dr. James on the Treatment of General Paralysis: II. The ChronicCase, will appear in this series next week.

The remedy is still in the stage of trial, and patients must be carefully selected.

Social and Medico-Legal Considerations.

The paretic is a difficult patient, especially in the early stages of the disease. He is often a danger to himself, his family, his fellows, and his fortune. Judgment is so defective that delusions flourish. The practitioner should warn the friends of the probability of disordered conduct, even where no signs of it have yet appeared. In addition to the excesses and extravagances of the elated patient, the depressed paretic may commit suicide, and the suspicious type may assault the innocent victim of his suspicions. Insight is quickly lost in the early paretic, and it is hopeless to argue with him. His promise to behave is quite valueless, and in his own interests certification should not be delayed too long.

Some of the slowly dementing patients and the tabo-paretics can be managed at home. Caution must be exercised in telling the relatives and friends the nature of the disease. In any case it is inadvisable to give a diagnosis until it is firmly established by careful laboratory examinations of the blood and cerebro-spinal fluid. No delay to vene-puncture and lumbar puncture should be sanctioned by the physician. In suitable cases energetic treatment should be urged, and in view of the impressive results of modern treatment a hopeless prognosis should not be given.

Not infrequently the wife of a paretic is fully aware of the nature of the disease and its course. She fears for herself and her children. Happily, the practitioner may safely reassure her. There is no danger to be feared from close contact with the patient, and no reason even to forbid sexual intercourse. The unfortunate patient has often been passed as medically fit for marriage, and unless there were active specific signs at marriage, and a history of miscarriages, the wife and children will invariably be found to be healthy. If the wife continues to be apprehensive, a family blood Wassermann may be taken, and a negative result is the rule.

If treatment is successful, the future life of a general paralytic should be carefully regulated. The diet should be simple, he should take gentle exercise in the open air, and the bowels must be kept active. He can, and often does, carry on his work after treatment and may continue to support himself and his family.

Careful notes of the mental condition should be made from time to time, and kept. Questions of business and testamentary capacity frequently arise, when some record of the mental state is useful, and it is often lacking when most wanted.

Lastly, the laboratory reports on the blood and cerebro-spinal fluid should always be filed, and refusal of treatment, a not infrequent occurrence, should be noted in the records made concerning the patient.

Temp. Lt. J. J. Seaton, Dental Surg., Gen. List, to be Lt.

ARMY RESERVE OF OFFICERS.

The following, having attained the age limit of liability to recall, cease to belong to the Res. of Off.: Col. P. McKessack, late R.A.M.C., and Lt.-Cols. R. L. Argles, H. L. W. Norrington, and J. H. R. Winder.

TERRITORIAL ARMY.

Lt. J. A. Fretton to be Capt.

Lt. J. Ledingham resigns his commn.

Lt. J. O'Hara, from the 52nd (Lowland) Divl. Train, R.A.S.C., to be Lt.

Supernumerary for service with O.T.C.—Capt. V. C. Pennell, late R.A.M.C., to be Lt. for serv. with Med. Unit, Cambridge Univ. Contgt., Sen. Div., O.T.C., and relinquishes the rank of Capt.

Capts. W. Johnson and E. T. Burke to be Majs.

Capt. J. McG. Johnson resigns his commn. and to retain his rank.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Cols. F. E. Fremantle and M. A. Cooke, having attained the age limit, are retd. and retain their rank, with permission to wear the prescribed uniform.

Capt. W. J. Wilkinson, having attained the age limit, relinquishes his commn. and retains his rank.

Hygiene Companies.—Capt. H. G. Moss resigns his commn. and retains his rank.

ROYAL AIR FORCE.

The undermentioned are granted permanent commissions in the ranks stated: Flight Lt. R. W. White and Flying Officer C. J. S. O'Malley.

The undermentioned Flying Officers are promoted to the rank of Flight Lt.: J. McM. Wilder and F. B. C. L. B. Crawford.

Flight Lt. F. T. Allen relinquishes his temporary commn. on account of ill-health.

Flying Officers: J. E. Foran to Headquarters, Egypt; and J. McCarren to Research Laboratory and Medical Officers' School of Instruction, on appointment to a Short Service Commission.

Flying Officers (D.): H. J. Eagleson to Station Headquarters, Andover; and A. P. McClare and S. McC. Craig to R.A.F. Depôt, Uxbridge, on appointment to temp. commns.

Flight Lt. D. Loughlin to School of Technical Training (Men), Manston.

ARMY MEDICAL SERVICE (R.A.M.C.): ERRATUM.—In the Students' Number of THE LANCET, published last week, the section of the Royal Army Medical Corps dealing with *Retirement and Retired Pay* and containing paragraphs numbered 1, 2, and 3 (p. 466) was inadvertently placed in the section on conditions in the Army Dental Corps. We regret the printers' error, while knowing that it will be detected immediately.

Special Articles.

SYNTHALIN IN THE TREATMENT OF DIABETES.

PRELIMINARY REPORTS TO THE MEDICAL RESEARCH COUNCIL.

THE substance known as "synthalin," which has been on trial as a substitute for insulin in Germany, and to some extent in other countries, during the past year, had its origin in the experimental investigations of Frank, Nothmann, and Wagner.[1] Starting from the fact that administration of guanidine is followed by a certain fall of blood-sugar, accompanied, indeed, by general symptoms of poisoning, these authors investigated a series of guanidine derivatives, in the hope of finding one which had an enhanced effect on the blood-sugar and a diminished general toxicity. From "agmatine" (guanidylbutylamine, obtainable by decarboxylation of arginine) they proceeded to higher homologues. The name "synthalin" was given to the compound of this series exhibiting the most favourable relation between efficiency in lowering the blood-sugar and general toxic action. The formula, which Prof. Frank communicated to the Medical Research Council before the commencement of the investigations here recorded, and which he is now about to publish, shows it to be a diguanidyl derivative of a long-chain aliphatic hydrocarbon.

Synthalin, being a pure, stable compound readily soluble in water, is absorbed without difficulty when taken by the mouth, and exhibits its characteristic activity under these conditions. If its action were truly insulin-like, and not attended by other drawbacks, this possibility of oral administration would obviously give it great advantage over insulin. The reports published from other countries are not uniform in their conclusions. The majority of the observers who have published their experience appear to have obtained results which have led them to attribute value to "synthalin" as a partial or, in mild cases of diabetes, even as a complete substitute for insulin. There are others whose experience has not been so favourable. There is some evidence, even in the records of treatment of human cases, of a toxic action on the liver, leading to the obvious warning against the employment of "synthalin" in diabetes complicated by cirrhosis. Many of the apparently favourable records are based on a disappearance of sugar from the urine rather than a lowering of the blood-sugar; and some cases have been treated as out-patients without effective control of the dietary intake. Under these conditions it was represented to the Medical Research Council that it would be desirable to have "synthalin" tested in this country on a series of cases under controlled conditions before it was offered to the medical profession generally. This suggestion had the support of Prof. Frank and of the manufacturers, who placed a suitable supply of the preparation at the Council's disposal for the purposes of such a preliminary trial. For this the Council invited the coöperation of a number of clinicians at different centres, to whom fractions of the available supply were distributed for the purposes of clinical tests.

Printed below are the separate reports which have been received from those taking part in the scheme of trials. The numbers of cases treated and the periods covered are as yet insufficient for any final conclusions to be drawn. The reports are accordingly to be regarded only as preliminary accounts. For the same reason, no attempt to correlate or summarise the findings of the different workers has been made at this stage.

One of the main difficulties encountered in the treatment of cases with "synthalin," by those responsible for its introduction, as well as other observers in different countries, has been the liability of the substance to produce anorexia, nausea, and consequent symptoms of depression. This trouble does not occur in every case, but is liable to impose a limit both on the daily dose of "synthalin" which can be administered and on the period for which its administration can be continued without intermission. Various efforts have been made to find other substances, the concurrent administration of which would mitigate this defect. According to the published accounts,[2] the most successful of these hitherto found appears to be sodium dehydrocholate, which has been introduced under the name "decholin." The stimulation of bile secretion by this bile-salt derivative is believed to have an antagonistic effect on the toxic action of "synthalin" on the liver, and the practical results of the combined treatment are said to be favourable. Unfortunately, supplies of "decholin" were not available in this country until most of the trials made under the Council's scheme had been practically completed. At the same time, it may be noted that there were few among the reported cases in which symptoms were produced by the "synthalin" treatment calling for the use of "decholin" as well.

While these clinical trials have been in progress experimental observations on the action of "synthalin" on normal animals have been in progress in the Biochemical Department of the National Institute for Medical Research. The full results of these will later be published elsewhere. In the present connexion it may be noted that the experiments have shown that in the normal animal "synthalin" has to be administered in doses producing a definitely toxic action on the liver, in order to produce a decided fall of the blood-sugar. Such results taken by themselves give the impression that its effect is mainly due to a depression of the new formation of sugar in that organ. Other experiments, however, carried out on the eviscerated, spinal preparation have produced evidence that "synthalin" also accelerates the disappearance from the circulation of glucose already present as such, though the glucose thus disappearing is not, as in the case of the insulin action, laid down in the tissues as glycogen, and large, toxic doses of "synthalin" are needed for demonstration of the effect.

Broadly speaking, the two sides of the insulin action—the depression of new formation of glucose in the liver and the accelerated metabolism of glucose already present in the circulation—appear to be represented in the action of "synthalin." The question of its practical use will obviously be decided by the degree to which its beneficial action is complicated by its toxic effects. It is clear that an ideal insulin substitute has not yet been obtained. "Synthalin," however, may be regarded, perhaps, as a partial success, giving at least a hope of further progress in the same direction.

REPORT FROM ST. BARTHOLOMEW'S HOSPITAL, LONDON, BY GEORGE GRAHAM, M.D., F.R.C.P., AND G. C. LINDER, M.D., M.R.C.P.

Synthalin has been used according to the method recommended by Frank, with some minor alterations, in order to test its action in comparison with insulin. Nine patients have been treated, seven of whom had been having insulin for some time. No patient has been treated for more than eight weeks, and these remarks cannot be regarded as anything but preliminary observations.

Cases not Receiving Insulin Treatment.

CASE 1.—A boy of 14 years, with mild diabetes for one year. On 80 g. carbohydrate he passed 20 g. sugar in the

[1] Frank, E., Nothmann, M., and Wagner, A.: Klin. Woch., 1926, No. 45; Deutsch. Med. Woch., 1926, No. 49 and 50.

[2] Adler, A.: Klin. Woch., No. 11, March 12th, 1927, pp. 493, 494.

urine with a high blood-sugar. After four courses of synthalin the glycosuria was reduced to a trace, and the blood-sugar was substantially lower although still above normal at certain times of the day. He had active tuberculosis.

CASE 2.—A woman of 57, with hypertension and obesity. The blood-sugar curve after 50 g. glucose was frankly of diabetic type before synthalin was given; after synthalin the curve, although still abnormal, was much less so.

Cases Receiving Insulin Treatment.

CASE 3.—A woman of 32, taking 35+30 units of insulin to metabolise 30 g. carbohydrate. After four courses of synthalin, a single dose of 20 units of insulin was sufficient to maintain the blood-sugar in the same range without glycosuria. After six courses the patient developed lassitude and nausea, and asked to return to insulin treatment.

CASE 4.—A man of 53, taking 25+25 units of insulin to metabolise 35 g. carbohydrate with normal blood-sugar. The patient has now taken 6 courses of synthalin with 10+10 units of insulin; the carbohydrate has been increased by 20 g., and he remains without glycosuria and with a normal blood-sugar.

CASE 5.—A severe case in a girl of 19, requiring 50+45+5 units of insulin to metabolise 20 g. carbohydrate and keep the blood-sugar normal. After three courses of synthalin the insulin was reduced to 30+25+5 units without harm, but no injection could be omitted.

CASE 6.—A boy of 15, taking 14+12+4 units of insulin to metabolise 32 g. carbohydrate with a normal blood-sugar. After three courses of synthalin, the insulin was successfully reduced to 5+5+5 units. It was not possible to omit an injection, for on 12+12 units of insulin sugar reappeared in the urine.

CASE 7.—A man of 30, who was having a diet containing 120 g. carbohydrate. With 20+20 units of insulin he passed 8 g. sugar. After three courses of synthalin, the glycosuria was rather lower and the blood-sugar was within the same range of limit.

CASE 8.—A boy of 16, who was having a diet containing 45 g. carbohydrate. The blood-sugar was kept within normal limits with 15+15 units of insulin. Synthalin, 25 mg. daily, was then given for three days at a time, with one day's rest. The insulin was gradually reduced to nothing, and the blood-sugar remained within normal limits. After six weeks he had an attack of nausea and vomiting, and synthalin has been stopped temporarily.

CASE 9.—A girl of 6, who was having a diet containing 30 g. carbohydrate. The blood-sugar could not be controlled with 10+10 units of insulin, on account of alternating hyper- and hypo-glycæmia. When synthalin was given instead of insulin, nausea developed together with a severe ketosis. This condition was treated with insulin and subsided rapidly.

Summary of Preliminary Work.—1. Synthalin has an effect on the blood-sugar which is not immediate like that of insulin, but is delayed and more prolonged. 2. Its action does not seem so consistent as that of insulin. 3. In one mild case 30 units of insulin were completely replaced by 25 mg. of synthalin, and the blood-sugar remained normal (Case 8). 4. In three cases a reduction of insulin dosage of 30–45 units was effected by 50 mg. of synthalin, and the blood-sugar remained within normal limits (Cases 3, 4, and 5). 5. In one case 50 mg. of synthalin had about the same effect on the urine sugar as 40 units of insulin, but the blood-sugar was not kept within normal limits (Case 7). 6. In two cases very little effect was apparent, and in a third the condition of the patient resembled that of incipient diabetic coma (Cases 1, 6, and 9). 7. Mild toxic symptoms were observed in two cases, but no decholin was available (Cases 3 and 8).

REPORT FROM GUY'S HOSPITAL, LONDON, BY E. P. POULTON, D.M., F.R.C.P.

The effect of synthalin was tried on two severe cases of diabetes, as there were no elderly cases with a mild diabetes in the ward at the time.

CASE 1.—A boy, aged 10 years, with diabetes for ten months. Two daily injections of insulin were given for a period of three weeks, 26 and 22 units. Then 10 mg. of synthalin were given twice a day for a week, and 20 mg. twice a day for 12 days. The patient began to get mild hypoglycæmic reactions, and the insulin had to be reduced to two doses of 16 and 12 units. The urine was tested at three-hourly intervals during the day, and was usually free from sugar. After omitting the synthalin, sugar appeared rather more frequently. Blood-sugar tests were carried out at 2 P.M. on different days; there was a good deal of variation in the results, but the average of four determinations before synthalin was 0·156 per cent., and during treatment with synthalin 0·135 per cent.—i.e., it was actually a little lower in spite of the insulin being reduced.

CASE 2.—A man aged 30. Diabetes had begun five years ago, and at the time he was treated successfully for coma. He was then treated by dietetic measures. He relapsed into coma associated with sepsis, and was admitted on March 25th, 1927. He required 40 units of insulin twice a day. The urine was nearly always sugar-free when tested at three-hourly intervals during the day. The blood-sugar at 2 P.M. was on an average 0·12 per cent. Synthalin was given in doses of 30 mg. twice a day, and the insulin reduced to 40 units once a day. There was usually some sugar in the 6 A.M. specimen of urine, and occasionally at other times with this treatment. The blood-sugar at 2 P.M. was 0·09 per cent. and 0·16 per cent. on two occasions. After ten days synthalin was omitted, but the insulin kept to 40 units once a day. The sugar came back in the urine in large quantities in every three-hourly specimen obtained during the daytime, and he began to complain of thirst.

Conclusions.—It is very difficult to draw conclusions as regards the effect of synthalin on the blood-sugar by making single determinations at the same time each day. What is really required is a series of determinations carried out through the 24 hours on several days; but so far as our determinations go, they suggest that the blood-sugar was no higher during synthalin treatment in spite of the insulin being lower. The therapeutic action of synthalin in diabetes is also shown by the urine tests and by the hypoglycæmic reactions of Case 1. At the same time synthalin can only be used in severe cases with the object of diminishing the number of injections. It would not be possible to do away with insulin altogether in these cases. These patients did not complain of indigestion with synthalin, but Case 2 complained of a dry throat.

REPORT FROM KING'S COLLEGE HOSPITAL, LONDON, BY R. D. LAWRENCE, M.D., M.R.C.P.

The effect of synthalin has been studied in six fully controlled diabetics by its effect on glycosuria, glycæmia, ketosis, nitrogen excretion, and the clinical condition. Synthalin was given for periods of from five days to four weeks in the fullest doses, 35 to 50 mg. per day, but without the usual pauses recommended by Frank, to obtain the fullest possible action of the drug. Little digestive intolerance has been observed, and no jaundice or urobilinuria. No decholin has been used to push the dosage still higher, because these cases were studied in February and March before the introduction of decholin.

Non-insulin Cases.

CASE 1.—A heavy glycosuria of 30 g. was produced by overfeeding in a mildly diabetic girl. This was reduced to 5 g. after four days of 40 mg. of synthalin and the blood-sugar from 0·25 to 0·2 per cent. but no further. She was subsequently easily controlled by diet alone.

CASE 2.—An excretion of 30 g. of sugar was reduced to 15 g. in a moderately severe diabetic after 45 mg. of synthalin for a week without any obvious change in the blood-sugar (0·22 per cent.) or ketosis. Subsequently 20 units of insulin completely controlled his condition.

Insulin Cases.

An attempt was made to replace insulin by synthalin in three moderately severe diabetics who required from 20 to 35 units respectively, a substitution which the German reports made appear possible. Synthalin alone in the fullest doses failed to control the diabetes, and a heavy glycosuria and ketosis and a marked hyperglycæmia and loss of weight followed in all three cases. On resuming insulin and synthalin together, synthalin seemed to spare 10 units in one case and perhaps 5 units in another. In one case, after stopping the insulin, alternating periods of ten days with and without synthalin were without any appreciable effect on the glycosuria, glycæmia, or ketosis during these periods. In a severe insulin-resistant case (220 units a day) 40 mg. a day of synthalin for three weeks failed to produce any effect in abolishing the need for insulin or sparing it.

Summary.—Among these six cases, it is only in the mild one, which could easily be controlled by diet alone, that synthalin had an important effect in reducing the glycosuria, without, however, making

the blood-sugars normal. In the cases who required even moderate doses of insulin, synthalin has not been able to replace insulin entirely nor to reduce it to one dose a day, which would be of great practical importance. Its continued use in any of the above cases had therefore no obvious advantage. It would seem from these results that synthalin can aid insulin action, if insulin either endogenous or exogenous is available, but cannot replace it. Thus it acted most in the mild case, less in the moderate cases in which it slightly increased the action of exogenous insulin, and failed in severe cases having little insulin.

It would appear probable, from *a priori* reasons and from the reports that synthalin can cause jaundice, that it acts by inhibiting the production of new sugar by the liver, an inhibition of catabolism, probably by a mildly toxic action on the liver cells. It seems unlikely that it can replace the anabolic function of insulin which is so essential to the diabetic. Its action in reducing the appetite may also be of importance in the results observed with uncontrolled diabetics. In my experience synthalin has proved of *no practical use* in the treatment of diabetes.

REPORT FROM THE LONDON HOSPITAL BY O. LEYTON, D.Sc., M.D., F.R.C.P.

I hold the view that in a certain proportion of cases suffering from diabetes mellitus the correct administration of insulin leads to regeneration of the pancreas; therefore I did not feel justified in trying the effect of synthalin upon all cases of that disease, but only when there was some definite contra-indication against insulin.

Amongst the dozen cases submitted to synthalin, (*a*) two were over 70 years old; (*b*) two had unstable metabolism, developing severe hypoglycæmic symptoms without any controllable cause—perhaps the effect of emotion upon absorption; (*c*) four cases had become tired of the frequent hypodermic injections; (*d*) three expressed a desire not to begin insulin, due to their having the incorrect impression that if insulin is begun it must be continued throughout life; (*e*) in one case huge doses of insulin had to be given, and I thought it wise to see whether synthalin could replace some of the insulin and thereby diminish the risk of severe hypoglycæmic attacks.

(*a*) In the two aged cases 25 mg. synthalin twice daily undoubtedly assisted the metabolism, shown by the acetone in the urine disappearing and the patients gaining weight whilst the glycosuria was reduced. The sugar in the blood was diminished but not reduced to normal. One of these cases, a female, developed symptoms which resembled those of acute cholecystitis, which subsided upon my ceasing to give synthalin. If this had been the only case developing such symptoms I should not have attached any importance to it because apparently the patient had had similar attacks in the past. The other case, a man, aged 75, was able to take 25 mg. synthalin daily but developed nausea when taking more. The 25 mg. assisted him to burn sugar but did not render him free from glycosuria.

(*b*) One of these two patients was a man whose work was intermittent and anxious. When at work, even if he succeeded in obtaining food, anxiety might prevent its absorption. Although intelligent and wisely refraining from insulin and food, nevertheless circumstances occasionally were too adverse and he had attacks. He gradually replaced 12 units of insulin twice a day by 25 mg. synthalin, whilst not making any alteration in the diet. The synthalin did not keep his blood-sugar at so low a level as the insulin, but seemed to raise his renal threshold for dextrose. Although the sugar in his blood was often in the region of 0·23 per cent. he did not pass a recognisable amount of sugar in his urine. He maintained his weight. The other, a boy of 14, who had been receiving 10 units of insulin twice daily for many months and had an occasional hypoglycæmic attack. Due to an infection, his condition became worse, and to meet this synthalin was given in addition to insulin with beneficial results.

(*c*) Of the four cases in this group, three were unable to take synthalin because they developed nausea and actual vomiting and this in spite of taking chloretone or dehydrocholic acid. One succeeded in continuing the drug when given two tablets of dehydrocholic acid with each dose of synthalin.

(*d*) A woman, aged 45, on diet C. 62, P. 72, F. 115, with sugar in blood 0·24 per cent. on synthalin 25 mg. twice a day gradually fell to 0·20 per cent. whilst the glycosuria was controlled. Chloretone failed to control the nausea and vomiting; 15 units of insulin twice daily led to hypoglycæmic symptoms developing; 10 units twice daily sufficed to prevent hyperglycæmia. A man aged 56. One year's history, treated by restricted diet. Placed upon a diet C. 67, P. 90, F. 130. Sugar in blood 0·25 per cent. After ten days on synthalin acetone disappeared from the urine, the blood-sugar was 0·24 per cent., and glycosuria persisted. Diet was reduced to C. 55, P. 90, F. 130. After a week traces of sugar were still passed along with a minute trace of acetone. These effects were produced whilst the patient was having teeth treated for pyorrhœa alveolaris. A woman aged 28. Six months' history. Diet C. 29, P. 84, F. 108. Sugar in blood, 0·20 per cent. After six days sugar in blood fell to 0·117 per cent. and glycosuria ceased. Diet then increased to C. 40, P. 84, F. 108. Several teeth extracted during period of treatment.

(*e*) A man, aged 33, with very severe progressive diabetes mellitus, needing more than 40 units of insulin twice daily to prevent hyperglycæmia and acetonuria. He was able to keep fairly well upon 30 units of insulin twice daily with two doses of 25 mg. synthalin. It is true that he developed nausea and a pain suggesting hepatitis. Synthalin was suspended for a time; for the last month or more he has been able to tolerate synthalin without the assistance of dehydrocholic acid or chloretone.

Conclusions based upon a dozen cases would be valueless, therefore I do not draw any.

REPORT FROM THE MIDDLESEX HOSPITAL, LONDON, BY T. IZOD BENNETT, M.D., F.R.C.P.

In the six weeks during which observations have been possible, only one case has been available from which detailed conclusions could be drawn. Six cases in all were observed, and toxic effects in the nature of gastro-intestinal irritation, nausea, vomiting, or diarrhœa were observed in three. These were not serious in degree, but sufficient to terminate the observations. Decholin was not available for use with the synthalin.

The case in which all controls were satisfactory was that of a child, aged 12, who has been under my care for five years. On a diet of C. 50, P. 70, and F. 100, with 15 units insulin, he is sugar-free with normal blood-sugar. Weight, 24 kilos. The insulin having been reduced to 5 units, the blood-sugar rose to about 0·20 per cent. and 20–30 g. sugar were excreted daily. Synthalin in doses of 15, 20, and 30 mg. daily was now given, increasing to the last dose over a period of 21 days. There were no toxic symptoms, and no effect was observed, either in the nature of a diminution in the urinary sugar or in the level of the blood-sugar. The synthalin was then stopped and the extra 10 units of insulin restored. In two days the patient was once more sugar-free with normal blood-sugar. It appears certain that in this carefully controlled case the synthalin was entirely without effect.

In another case it became evident that a reduction in sugar-excretion which had appeared to be due to synthalin was in reality due solely to the "ladder diet." This patient, after becoming nearly sugar-free on a diet of 500 calories, became quite sugar-free on a diet of 750 calories with 50 mg. of synthalin, but increasing tolerance had begun before the drug was given, and after stopping the synthalin the patient remained sugar-free and the diet was raised gradually to 1000 calories without glycosuria returning.

Conclusions.—1. No case has been observed in which a reduction in sugar excretion or of hyperglycæmia could be ascribed to the administration of synthalin. 2. In a most carefully controlled case of severe diabetes, synthalin in full doses appeared to have no effect. A small dose of insulin in this same case produced effect with almost mathematical exactitude. 3. Controls such as absolutely fixed diet over a sufficient preliminary period are essential if correct conclusions are to be drawn as to the possible effects of drugs of this type. 4. The absence of all gastro-intestinal symptoms is a further most important control condition, it being evident that even a slight degree of anorexia or gastro-intestinal disturbance may produce a diminution of sugar excretion. 5. The number of cases at present observed is far too small to permit of any final conclusion being drawn.

A portion of the synthalin received was handed to my colleague, Prof. E. C. Dodds, who tested it on rabbits, both orally and by subcutaneous injection. Oral administration proved ineffective. Given subcutaneously in doses of approximately 5 mg. per kilo body-weight, no effect was observed. In doses

exceeding this death occurred, the blood-sugar, after a preliminary hyperglycæmia, falling to below 0·05 per cent. Intravenous administration of glucose failed to save the animals. Histological examination of the organs is in progress.

REPORT FROM ST. THOMAS'S HOSPITAL, LONDON, BY PROF. HUGH MACLEAN, D.Sc., M.D., M.R.C.P.

Synthalin was tried on eight diabetic patients. The doses were from 10–20 mg. twice daily, with an occasional day on which no synthalin was given. In five of these patients the drug set up fairly marked clinical symptoms within four or five days so that its use had to be discontinued. This toxic action seemed to affect chiefly the gastro-intestinal tract, and the chief symptoms complained of were nausea, anorexia, vomiting, and diarrhœa. Occasionally slight albuminuria was noticed, but this was always in very small amount. Even when no definite symptoms were present several of these patients complained that they did not feel well; they said they were "out of sorts" but could not give a more definite description of their feelings.

In three patients, however, the use of the drug gave rise to no toxic symptoms of any consequence. The plan adopted in these cases was to stabilise the patient on some definite treatment, then to give synthalin; and after synthalin was administered for some time it was withdrawn for a period. The following are the results obtained in these three patients:—

CASE 1.—Aged about 57. This patient had a history of thirst, wasting, and weakness for nine months. On admission to hospital the urine contained large amounts of sugar and diacetic acid. The patient was given a suitable diet and watched for some time. For four days before synthalin was given careful records of the blood-sugar, volume of urine, sugar excretion per day, and acetone secretion per day were kept. The results obtained were as follows:—

Results for Four Days Before Synthalin.

Blood-sugar averaged	0·28 per cent.
Volume of urine	2300 c.cm.
Average sugar in urine per day	75 g.
,, ketones per day	9·6 g.

The patient was then given 10 mg. of synthalin twice a day and records were kept as above. Since synthalin does not appear to act immediately, the results for the first three days on synthalin treatment are given separately. After this the results for the six following days are recorded:—

Average Results for Three Days with Synthalin.

Blood-sugar averaged	0·28 per cent.
Volume of urine per day	1300 c.cm.
Total sugar per day	56 g.
,, ketones ,,	7·5 g.

Average Results for following Six Days with Synthalin.

Blood-sugar averaged	0·24 per cent.
Volume of urine per day	1200 c.cm.
Total sugar per day	40 g.
,, ketones ,,	3 g.

After this synthalin was withdrawn. The following are the results obtained for the next four days:—

Average Results for Four Days following Withdrawal of Synthalin.

Blood-sugar averaged	0·3 per cent.
Volume of urine per day	1600 c.cm.
Total sugar per day	70 g.
,, ketones ,,	5·5 g.

In this patient synthalin had apparently a marked effect on the excretion of ketone bodies. There was also some effect on the amount of sugar excreted. With the exception of some slight feelings of nausea on one or two occasions this patient had no toxic symptoms from the drug.

CASE 2.—This was a severe case of diabetes in a female aged 21. When admitted to hospital the patient was taking 75 units of insulin per day. In this patient blood-sugars were systematically estimated at 10 A.M., 1 P.M., and 4 P.M. each day. For a fortnight she was kept on standard diet with 75 units of insulin per day. After this synthalin was added and given for ten days. The insulin was then reduced to 40 units per day, the same amount of synthalin as before being given. After this the synthalin was cut off. In a few days more synthalin was again added. On the whole the variations in blood-sugar were not very different whether synthalin was given or not, so it is unnecessary to give the figures. The general results obtained in this patient are as follows.

Standard Diet and 75 Units Insulin for 14 Days.

Average amount of urine per day	1900 c.cm.
,, sugar passed per day	48 g.
,, ketones ,, ,,	4 g.

Synthalin, 20 mg., Twice Daily, with 75 Units Insulin, for Ten Days.

Average urine per day	1400 c.cm.
,, sugar ,,	23 g.
,, ketones ,,	0·8 g.

Insulin, 20 Units, Twice Daily, with Synthalin as Before.

Average urine per day	800 c.cm.
,, sugar ,,	10 g.
,, ketones ,,	0·58 g.

Synthalin, Cut Off; Insulin, 20 Units, Twice Daily as Before.

Average urine per day	1700 c.cm.
,, sugar ,,	56 g.
,, ketones ,,	2·7 g.

Synthalin, 20 mg., Twice Daily, with Insulin, 20 Units, Twice Daily as Before.

Average urine per day	800 c.cm.
,, sugar ,,	40 g.
,, ketones ,,	0·3 g.

In the case of this patient, although there was no appreciable variation in the blood-sugar, it is obvious that the total excretion of sugar was reduced when synthalin was begin given. The most marked effect of the drug, however, appeared to be on the acidosis. The reduction in the amount of ketone bodies which followed the administration of synthalin is very marked.

CASE 3.—This patient was a female, aged 40, with a history of diabetes of 18 months' duration. In this patient synthalin did not seem to have any marked effect but the drug was not continued for more than five days owing to albuminuria resulting. It is interesting, however, that this patient did not experience any gastro-intestinal symptoms.

Conclusions.—From the point of view of practical therapy, synthalin in its present form is of little or no value because of its pronounced toxicity when given in doses sufficiently large to have an effect on the metabolism. There can be little doubt that synthalin has a very definite though perhaps limited effect in certain cases of diabetes. It appears to reduce to some extent the excretion of sugar and seems to have a very pronounced effect in reducing ketone bodies in the urine and in limiting acidosis. Whether these results are obtainable only in certain patients, or whether all patients react in the same way, was impossible to decide owing to the toxic properties of the drug.

REPORT FROM THE ROYAL INFIRMARY, BRISTOL, BY MAURICE E. J. PACKER, B.Sc., M.B.

Six cases of diabetes mellitus were chosen to represent all degrees of severity of the disease, the patients' ages ranging from 16 to 69. The drug was given by mouth in varying doses (up to 100 mg. in one day), and both with and without insulin. Each case was treated for about three months and frequent blood-sugar curves were taken after the standard meal.

Case.	Age.	Sex.	Weight.	Severity.	Diet in grammes.		
					C.	P.	F.
1	50	F.	12·13	Medium.	93	76	165
2	16	F.	9·8	Severe.	69	57	129
3	59	F.	8·3	Medium.	69	57	129
4	48	F.	12·7	Medium.	93	76	165
5	69	M.	11·2	Slight.	124	101	218
6	54	M.	10·8	Medium.	124	101	218

CASE 1.—With 15 units of insulin b.d. the maximum blood-sugar was 0·278 per cent. with no glycosuria. Synthalin, given in addition, failed to lower the blood-sugar. Glycosuria was caused by trying to replace 15 units of insulin by 75 mg. of the drug every day for three weeks.

CASE 2.—The maximum blood-sugar was 0·260 per cent. with 56 units of insulin twice daily. The addition of 50 mg. of synthalin on alternate days raised her blood-sugar.

CASE 3.—The maximum blood-sugar was 0·289 per cent. with intermittent glycosuria; 50 mg. of synthalin every day did not take the place of 10 units of insulin, for the blood-sugar and glycosuria were increased.

CASE 4.—This patient had not been treated with insulin. She could not tolerate more than 20 mg. of synthalin on alternate days and this dose caused the blood-sugar to fall from 0·279 to 0·250 per cent. A daily glycosuria of about 50 g. decreased to about 20 g. Pruritus vulvæ was not markedly improved.

CASE 5.—His blood-sugar curve (fasting B.S. — 0·185 per cent.) was slightly improved by 20 mg. of synthalin on alternate days. He could not tolerate more. Glycosuria was rarely found before or during treatment. Neuritis was not improved.

CASE 6.—The blood-sugar curve (max. B.S. — 0·286 per cent.) was only slightly improved by 50 mg. of synthalin each day. Diabetic cataracts continued to become worse.

Conclusions.—This short series indicated that: 1. The preparation does not cause a pronounced and sustained fall in the blood-sugar level or glycosuria. 2. Neuritis and pruritus vulvæ of diabetic origin are not improved by the drug. A case of diabetic cataracts continued to become worse. 3. Toxic effects are easily produced, but in time patients are able to stand progressively larger doses. 4. Synthalin (given by mouth) was not a satisfactory substitute for insulin in the cases treated.

REPORT FROM THE ROYAL INFIRMARY, MANCHESTER; THE ROYAL HOSPITAL, SALFORD; AND THE ANCOATS HOSPITAL, MANCHESTER, BY G. J. LANGLEY, M.D., M.R.C.P., AND GARFIELD THOMAS, M.SC.

(The cases at the Manchester Royal Infirmary were made available by the kind coöperation of Dr. F. Craven Moore, Dr. E. Bosdin Leech, and Dr. A. Ramsbottom. Those at the Salford Royal Hospital and Ancoats Hospital were under the care of Dr. Langley.)

Nine cases have been treated. Two children, ages 13 and 15 years; four young adults, ages 24, 28, 34, and 37 years; and three in late middle age—i.e., two aged 51, and one 67 years.

Progress has been estimated by determination of the blood-sugar, the examination of the urine, maintenance of the body-weight, and general condition of the patient.

In the cases treated at Ancoats and Salford Hospitals the blood-sugar was estimated two-hourly except at night. The general plan was to build up the patient's diet with an adequate dose of insulin and then when balance had been established to change over to synthalin by Frank's method, the diet remaining unchanged. Periodical remission of the synthalin, as recommended by Frank, was carried out. Two of the cases have been under synthalin treatment for 11 and 12 weeks respectively, and the other seven for nearly four weeks.

In the two children and two of the young adults synthalin failed to control the disease—i.e., it was not possible to replace the insulin with the equivalent or more than equivalent dose of synthalin (50 mg. daily was not exceeded) and maintain the blood-sugar at a satisfactory level. In one of these cases, a moderately severe type, the toxic effects of the drug when 50 mg. daily were being given, necessitated a return to insulin. Decholin was not available.

In one of the young adults, a female, aged 28, 30 units of insulin daily have not been replaced satisfactorily by 50 mg. of synthalin because the blood-sugar has shown a tendency to rise. In this case judgment must be reserved until a later date.

One of the young adults, a butcher, aged 37, admitted in coma, was brought into balance with 70 units of insulin daily. This patient has had synthalin for 12 weeks, 50 mg. being given to replace 40 units of insulin. His balance has been maintained, and his condition is satisfactory.

Of the three older patients, one brought into balance with 40 units of insulin per diem has had this satisfactorily replaced by 50 mg. synthalin. The blood-sugar has kept within normal limits, the patient's weight is maintained, he has had no toxic symptoms, and is back at work. Another of the older patients requiring 24 units of insulin daily had this replaced by a single dose daily of 25 mg. of synthalin. After apparent successful replacement lasting nine days, acute toxic effects were produced and the drug was stopped. In this case, after cessation of the vomiting and diarrhœa, the blood-sugar has remained normal for a period of ten days *without either synthalin or insulin.*

The third case in this group was a patient, aged 67, who had been operated on for diabetic gangrene, the diabetes being controlled by 40 units of insulin. This was successfully replaced by 50 mg. of synthalin. After eight days half this dose was found to be equally successful, and for a further 12 days neither drug has been used. The blood-sugar has remained normal and weight has been maintained.

Summary.—It will thus be seen that in four out of the nine cases the synthalin has been unsuccessful. In one, the result is as yet doubtful but promising. In two others, the synthalin has replaced insulin apparently satisfactorily, but in one of these insulin is still required though in a smaller dose than previously. Finally, in two more cases, control appeared to have been established with synthalin, but on ceasing to administer either synthalin or insulin the blood-sugar remained normal. This is in accordance with the general experience that the diabetic in later middle life after insulin treatment for from three to four weeks will remain sugar-free and comfortable for a considerable period without continued insulin. On the other hand, it is known that the effects of guanidin last for a long time, and this may be true of synthalin. In two of the cases toxic effects were produced, and the treatment had to be abandoned on this account.

REPORT FROM THE ROYAL INFIRMARY, EDINBURGH, BY PROF. D. MURRAY LYON, D.SC., M.D., AND W. ROBSON, PH.D., M.SC.

Papers already published regarding the value of synthalin in diabetes are unconvincing because sufficient care does not appear to have been given to control of the diet during the tests. In many of the cases illustrated the composition of the diet has been varied from day to day, allowing insufficient time for thorough stabilisation. The full effect of an alteration of the food intake does not become at once apparent, and a steady balance may not be reached for a week after a change has been made. In submitting a new drug to clinical test it is essential that the effect of other variables be avoided, and in the case of an insulin-like body this necessitates a rigid control of the diet during the period. For these reasons, cases of considerable standing who had been under observation for a long time were chosen. The patients were already stabilised and sugar-free on a standard diet of definite caloric value either with or without the aid of insulin. By raising the diet or by reducing the insulin a small quantity of sugar was then allowed to appear in the daily sample of urine, and the patient was stabilised afresh during a week at this new level. Synthalin was then administered over periods of from five to seven days, and this was followed by similar periods without and with synthalin. Under these circumstances there appeared to be a slight reduction in the quantity of sugar excreted under synthalin, but traces of glycosuria were never finally got rid of. In none of the five cases so examined has the effect been striking. On the other hand, three of the patients have been a good deal upset by the drug. Headaches were frequent and severe, and there has been considerable nausea, retching, and vomiting. At times the observations have been rendered doubtful by the patient losing food through anorexia and vomiting, or through failure to digest it completely. Those symptoms are so disturbing that they will restrict the free use of the drug, should it prove to possess the other actions claimed for it.

One other case has been treated with synthalin from the beginning. He was put on a diet of 2000 calories containing 68 g. of carbohydrate, and this has been kept constant throughout the investigation. During five days without synthalin the daily loss of sugar fell from 400 to 300 g. Synthalin was then given for eight days, and the daily output gradually fell to about 30 g. A period of seven days without synthalin followed and the sugar loss further diminished to 9–20 g. a day. Observations are being continued. How much of this improvement is to be attributed to continued use of the rather low diet, and how much to the drug, is not yet apparent. Synthalin merits further investigation, but our experience of it up to date is not sufficient to allow of any opinion as to its real value.

THE CAMPAIGN AGAINST MALARIA.

THE Second General Report on the Principles and Methods of Antimalarial Measures in Europe[1] has just been published by the Malaria Commission of the League of Nations, and is dedicated to Dr. N. V. Lothian, Dr. S. T. Darling, and Mlle. A. Besson, who died whilst travelling on duty on Lebanon. The collective study-tours undertaken by the Commission have for the first time enabled malariologists of different countries and of different schools of thought to study local problems on the spot. Individual views have become modified and the conclusions reached in most cases represent an average opinion which probably approaches the truth. Their significance is obvious, and they do not apply to Europe alone.

Only very rarely, it is pointed out, can there be any question of converting a malarial into a non-malarial place; an alteration of this kind can be effected only by a complete change in the character of a site such as has occurred in the course of centuries in London and Rome. In the Panama Canal zone, for instance, the locality has not been essentially altered, and malaria is merely being held in check; were protective measures to cease, the disease would again become devastating. Save in very exceptional cases, therefore, it is unwise to aim at more than a significant reduction in malaria—that is to say, a reduction which will make it of little or no importance as a cause of sickness and death. As regards the means by which this may be accomplished, the startling statement is made that there are localities where hardly anything has retarded the effective control of malaria so much as the belief that, since mosquitoes carry the infection, their elimination should be the object of chief concern and expenditure. In England, the Netherlands, and Denmark malaria was robbed of its importance at a time when its epidemiology was unknown, and when there was no reduction of mosquitoes, and the Commission has seen the same thing happening in Europe to-day.

Of the measures which may be employed for the lessening of malaria, there is none which can be described as the method of unquestioned choice, and the one selected must depend on local conditions. Yet such measures do fall into two great categories, designated direct and indirect, these terms being used in rather special senses. The direct measures of the Commission are those which kill malaria parasites, either in man by the treatment of infected persons, or in anopheles by the destruction of infected mosquitoes in houses. In the opinion of the Commission, these direct measures are primary and always indispensable; the others are adjuvant. The old aim—to break the chain somewhere—is replaced by a new one, to kill the parasites themselves. Nor is it held advisable that too many different measures of control should be put into operation at the same time. It is better to carry out one or two thoroughly, for experience has shown that for every measure there is a "minimum effective degree of perfection," and if it is not carried out with a certain degree of thoroughness then it is of no use at all.

For the destruction of plasmodia in the human body it is stated that quinine, quinidine, and kinetum are of almost equal efficiency in dosage of 1 g. daily, while cinchonine falls into the same category if the dosage is increased to 1·5 g. Quinidine is the strongest cardiac depressant. Kinetum consists almost entirely of residual alkaloidal bases—the composition of the tested samples being: quinine 15, cinchonidine 35, cinchonine 25, quinidine 5, and quinoidine 20 per cent.—and it must, therefore, be concluded that a standard preparation of the principal alkaloids, purified only so far as to exclude the more toxic constituents, is as efficacious as quinine. This conclusion replaces the cinchona febrifuge of India and Java in its old eminence, always provided that it can be standardised; and it is also important because employment of these total alkaloids, in place of pure quinine, would greatly enlarge the amount of specific antimalarial alkaloid at present available for world use, and—apart from commercial rings—should correspondingly cheapen the cost of treating the disease. The demand for, and so the cost of, cinchona alkaloids will be further reduced by the Commission's pronouncement that "prophylactic quinine" in the usual preventive doses does not prevent malaria, and merely does something to keep in abeyance an infection which has become established. In these ways more and cheaper alkaloid should become available for use where its action is most greatly to be desired. All this implies the primary importance of diagnosis, and the Commission indicates administrative methods which would make for its accuracy.

The procedure advised for directly attacking plasmodia in anopheles starts from the fact that, in Europe at any rate, the majority of infected mosquitoes are found inside houses. Many a housewife offers to *Anopheles maculipennis* the amenities of cobwebs, dirt, dark corners, and shady cupboards, whereas the gorged, sluggish, and probably infective mosquito ought really to be regarded with as much disfavour as the bed-bug and the louse. It is difficult to exaggerate the importance of their destruction, and at least they ought to be put to all possible discomfort by house-cleaning and whitewash. It may also be noted that the Commission is satisfied of the usefulness of the suggestion—associated particularly with the name of Roubaud—that a damp, dark, still animal house situated between a breeding-ground and the home will divert the insects to a harmless vicarious meal.

With regard to indirect antimalarial measures the Commission states that in all its journeys only two regions have been found where efforts of this kind on a large scale have been definitely successful—namely, in the Karst Mountains of Dalmatia, and in parts of Palestine. In both of these areas water is extremely scarce, strictly localised, and readily controlled. The report returns to the subject of Italian bonification, which signifies all work carried out with the object of making regions which are periodically or permanently marshy, more suitable for agriculture and more healthy. The means adopted are not essentially antilarval, and indeed they often increase, by the use of drains, the total area available for anopheline breeding. Their object is primarily social—that is to say, they change a poor, sparse, scattered, often semi-nomadic, population into one which is settled, well-to-do, and aggregated into villages, and has schools, doctors, water-supply, proper sewage disposal, and houses of an enforced hygienic standard. With a change of this kind malaria is lessened.

Finally, the Commission emphasises the great need for continued research. It is remarked that the conveyance of malaria in the natural way by mosquitoes in this country, in cases of general paralysis, has enabled English workers to make certain valuable and unique observations. The unnatural method of infection practised elsewhere—namely, injection of the blood of a malarial subject—has not permitted similar studies abroad. These observations, together with an account of work in the Netherlands, Roumania, and Italy are embodied in the report, and the whole forms one of the most stimulating publications on malaria that has appeared in recent years.

KING'S COLLEGE HOSPITAL. — King's College Hospital will require a larger income this year than its total of £102,554 of last year if it is to meet the cost of additional beds and the pension scheme. The necessity of completing the building, owing to the demands of the ever-increasing population of South London, is strongly emphasised by the Committee. The in-patients treated last year numbered 6055 and the number of new out-patients 34,492.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Medical Registration.

THE first step in the formation of the Irish Free State Medical Registration Council was taken last week, when the election of two direct representatives of the medical profession was completed. Three candidates were nominated—namely, Mr. P. E. Hayden, F.R.C.S.I., Prof. M. R. J. Hayes, F.R.C.S.I., and Prof. R. J. Rowlette, F.R.C.P.I. There are on the Register some 2900 practitioners entitled to vote. Of these, only about half returned voting papers. The count showed 1141 votes cast for Mr. Hayes, 936 for Dr. Rowlette, and 552 for Mr. Hayden. Mr. Hayes and Dr. Rowlette were, therefore, declared elected. Invitations have been issued by the Minister to the several educational bodies who are entitled to nominate representatives to notify him of the names of their nominees. When these have been received the Executive Council will complete the Council by two further appointments.

Election of Mr. T. Hennessy to the Dail.

Mr. T. Hennessy, F.R.C.S.I., has again been elected a member of the Dail. He had been one of the deputies for South Dublin City from early in 1925 up to the General Election, when, acting on medical advice, he refused to go forward again as a candidate. A vacancy having since occurred in his old constituency, he consented, at considerable personal inconvenience, to contest the seat. His many friends in the medical profession rejoice that he was successful, winning for the Government Party by a larger majority than was expected. It is somewhat hard on him that the Dail should have been dissolved immediately after his election, as he will have to face another election in a fortnight's time. The medical profession, regardless of party, recognise the importance of having in the Dail a medical man of the authority and influence of Mr. Hennessy, and his return at the general election is to be hoped for.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Vital Statistics.

THE birth registration area last year comprised 28 States, and within this area 1,597,903 births were reported, giving a general birth-rate of 20·1 per 1000, as compared with 21·1 during 1925. Florida has the highest birth-rate (26·4), perhaps as a result of the recent boom, and is the only State where there has been an increase. Florida also shows the highest death-rate (15·3). The general death-rate for the registration area has increased from 11·7 per 1000 in 1925 to 12·1 in 1926, and infant mortality has increased from 71·5 to 72·8 per 1000 births for the same years. Arizona, which is becoming popular as a health resort, has the highest infant mortality (119·5) of any of the 28 States reporting. Homicide is more than ten times as common as in England, and even when the coloured population is excluded the rate remains seven times that for England and Wales. For 28 cities with an aggregate population of nearly 23,000,000 the murder death-rate was 9·9 per 100,000, as against 11 per 100,000 in 1925. Compared with the previous year there has been a decrease in Chicago from 18·8 to 16·7, in New York from 6·4 to 5·7, and in Philadelphia from 9·7 to 8·6. Dr. F. L. Hoffman, commenting in the *Spectator* on the 1926 homicide statistics, remarks that capital punishment is apparently no deterrent, for there is, generally speaking, a higher murder death-rate in the States which enforce it.

Industrial Morbidity in Ohio.

The Industrial Commission of Ohio is authorised to set aside from the State insurance fund a sum of money not to exceed 1 per cent. of the annual contributions made by employers for the investigation and prevention of industrial accidents and diseases. With this fund the commission has set up a division of safety and hygiene including statistical, medical, and research branches, and the first comprehensive study of the industrial morbidity of the State has now appeared.[1] Between July 1st, 1921, when the compensation law became effective, and Jan. 1st of the present year, 4443 claims have been filed. These claims have been classified according to the nature of the disease or accident, the industry in which it occurred, and the duration of disability. From the last point of view lead-poisoning is found to be the most serious cause of economic loss, 907 claims showing a total loss of 277,112 days. This figure includes fatalities (37) and permanent disabilities, the time-loss for which is calculated according to the scale of weights recommended by the International Association of Accident Boards and Commissions. Skin diseases, on the other hand, were responsible for the largest number (3005) of claims, but for a total loss of only 86,253 days. Most of the cases in this group (2890) were due to dermatitis from various irritants, including gases, dusts, and oils. The duration of disability from this cause was less than one week in 57 per cent. of the claims. A number of claims were filed which cannot be compensated under the present law, including 75 for tuberculosis, with 14 deaths. Although this list is obviously incomplete it has also been classified and the results included in the tables. The total loss of time by all compensable claims was 760,069 days, and the total medical expense for treatment of these cases was $98,866. Unfortunately the number of insured persons is not given either by industries or in total.

During the past year 3692 claims have been made for injuries to minors (under age 18), of whom 3139 were males. As many as 233 claims were for children under 16 years of age. Classification of the claims shows that a number of minors must be illegally employed. For example, no child under the age of 18 years may oil or clean machinery while in motion, or operate abrasive wheels in the manufacture of metal articles, yet a number of accidents occurred to minors while engaged in these occupations. The causes responsible for the greatest frequency of accidents are given as handling objects (839 accidents), machinery (831), stepping upon or striking against objects (485). The causes responsible for greatest severity of accidents are motor vehicles (21,034 days), elevators (20,781 days), and machinery (19,880 days). The accidents by machinery are further classified according to the type of machine. Once again the value of these tables is diminished by our ignorance of the numbers exposed to risk.

Immunisation against Diphtheria.

The Board of Health of the State of Virginia has devised a plan for encouraging the general use of toxin-antitoxin for the prevention of diphtheria. Attached to every birth certificate is a piece of paper bearing the legend: "When the baby is six months old have your doctor give toxin-antitoxin to prevent diphtheria.—United States Public Health Service." The Federal authorities recommend that other States should follow this example.

A Campaign against Venereal Disease.

In the *Chicago Evening American* for August 8th appears a full-page advertisement of a public health institute, organised for public service as a corporation not for profit under the laws of the State of Illinois. The names of the trustees of the institute appearing at the foot of the advertisement are those of prominent business men in the city. "It's a crime," the headline reads, "to expose innocent women and children to the ravages of 'social' diseases." Advice is given on the contagiousness of these diseases, an illustrated booklet is offered free to applicants, and

[1] Special Bulletin No. 1. The Industrial Commission of Ohio, 1927.

the addresses of three treatment centres are given with the assurance that the treatment will be given privately by competent physicians at prices which all can afford. This is an interesting, because rare, example of a local public health organisation founded and sponsored by the laity from a sense of public responsibility.

A Notable Propagandist.

The return of Dr. W. W. Peter from China recalls his remarkable health campaign at Foochow in 1920. During a single week 110,000 people were reached through 247 meetings, and the result was practically to eradicate cholera from a city where it had long been endemic, and where in 1919 there had been no less than 18,000 cases. Dr. Peter has now joined the staff of the American Public Health Association as associate secretary.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the statistics for 1926 of three Scottish towns :—

Name of district and mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Diarrhœa under 2 years.	Infant mortality.	Maternal mort. from childbirth.
Glasgow .. .. (1,101,622)	22·1	14·2	1·17	1·26	2·8	1·4	6·5	104	6·3
Aberdeen .. .. (158,723)	21·5	13·3	1·15	1·33	1·67	—	4·5	96	5·9
Paisley .. .. (86,103)	22·4	14·2	1·03	1·68	2·7	1·5	9·8	114	4·7

The population of Glasgow, as shown, is a local estimate. The Registrar-General's estimate is lower, and makes the birth-rate 23·5 and the death-rate 15·1. The neonatal rates in the three towns are : Glasgow, 37 ; Aberdeen, 35 ; and Paisley, 47. A table in the Aberdeen report gives the death-rates from all causes in the six chief Scottish towns, when corrected for age and sex distribution, as : Glasgow, 17·0 ; Edinburgh, 13·7 ; Dundee, 14·8 ; Aberdeen, 13·4 ; Paisley, 15·6 ; and Greenock, 15·0. It is to be hoped that after the 1931 census the discrepancy between central and local estimates of population will disappear. An over-estimate of the population is perhaps more dangerous than an under-estimate, as it may lull the local health authority to a sense of false security.

Glasgow.

Dr. A. S. M. Macgregor's report is a volume of 375 pages, which includes many interesting special reports by members of his staff. By the Glasgow Boundaries Act of 1925 10,328 acres were added to the city. The population of the added area was only two persons per acre, whereas that of the 19,183 acres of the old city was 57. The average density of the extended city is therefore 38 persons per acre. The number of empty houses in the old city in 1926 was 408, and in the extended city 421 ; in 1913 the number of empty houses in the old city was 18,710. A total of 6796 linings for new houses were granted by the Dean of Guild Court, a much higher number than in any year since the war, although, says Dr. Macgregor, "the rapidity with which the shortage is being overtaken is not yet sufficiently great." The worst feature of the housing situation is the intense overcrowding of the small houses. The effect of some of the slum clearance schemes is illustrated by plans and photographs. A scheme came into operation on July 1st, 1926, for the admission of candidates from Glasgow and south-west Scotland to the Royal Blind Asylum for training. During the last half of the year 49 applicants were dealt with, of whom 14 were found not to be blind according to the standard adopted. The causes of blindness in the 35 candidates accepted were as follows : Congenital cataract, 2 ; senile cataract, 3 ; albinism, 1 ; aniridia, 1 ; syphilis, 11 ; gonorrhœa, 4 ; measles, 2 ; pneumonia, 1 ; glaucoma, 1 ; injury, 2 ; and cause unknown, 7.

A booklet has been prepared during the year describing the maternity and child welfare scheme with all its ramifications. A chart showing the infant mortality-rate since 1890 shows the large oscillations which occur from year to year, "due to the effect which infectious and respiratory diseases have on infant life." During 1890 to 1900 the oscillations were round about 150 ; now they are round about 100. Dr. Macgregor states that a study of the last epidemic shows that under the close association permitted by tenement life in closely congested areas, measles, with its complication broncho-pneumonia, attacks the children at an age when they are relatively powerless to resist it. Another chart in the report shows the regularity with which an outburst of measles occurs every alternate year. An effort is being made to secure better coöperation with the education authority by the establishment of joint clinics. An illustration is given of the new welfare centre opened at West Govan during the year. There are now 14 centres at which consultations are held, and the child welfare staff includes 10 lady doctors and 29 nurses. An investigation has revealed the fact that between 4 and 5 per cent. of the children attending the welfare centres suffer from some degree of otorrhœa. It was noted that in 48 per cent. the condition began in the first year of life (in 22 per cent. before the end of the sixth month) ; in 27 per cent. during the second year ; and in the remaining 25 per cent. between the third and fifth years. In 70 per cent. of the cases occurring before the end of the second year the cause given was either dentition, debility, or unknown. In about 19 per cent. of all the cases disease of the naso-pharynx was stated to be the cause, whilst in 12 per cent. one of the infectious diseases—measles, scarlet fever, whooping-cough, diphtheria—was stated to be the cause. In more than half of the cases the otorrhœa was associated with enlarged tonsils and adenoids. The number of women who have attended the antenatal dispensary shows an increase from 3878 in 1925 to 4266 in 1926, and 866 cases were admitted to the antenatal wards in 1926 as compared with 730 in 1925. Antenatal consultations are now held at six centres, and the primary attendances at these centres numbered 2144 during the year, about 15 per cent. of the patients being primiparæ. The maternal death-rates per 1000 births during the last five years 1921–25 have been : in Glasgow 6·39, 7·60, 7·08, 5·84, and 7·63 ; and in Scotland 6·38, 6·60, 6·42, 5·82, and 6·16. During the last six years the death-rate from puerperal sepsis in Glasgow is given as 2·32, 3·00, 2·55, 2·21, 2·32, and (in 1926) 2·8. Dr. Macgregor points out that increase in cases indicates an improvement in notification. Of the 24,000 births over 11,000 were attended by midwives, who sent for medical help in 25 per cent. of their cases. Only about 13 per cent. of the ophthalmia neonatorum swabs examined were found to be gonococcal. The gonococcal cases numbered 99 and the resulting damage to eyesight was blindness in one eye in two cases and corneal scars in two others. The 386 non-gonococcal cases recovered without injury to eyesight. A maternity home had to be closed during the year owing to a serious outbreak of puerperal fever. There were ten cases of puerperal fever with four deaths and two cases of erysipelas with one death. The home was a well-equipped one, with accommodation for 20 patients, but the incident "raised important questions of medical administration concerned chiefly with late diagnosis and notification and certain details connected with the management of patients."

These defects were remedied in a thoroughly satisfactory manner before the reopening of the home.

Typhus fever returned after an absence of three years and there were eight cases. The disease was mild in the younger patients, but severe in the older, and resulted in one death. The outbreak has been fully reported in THE LANCET (1927, i., 887). The notifications of enteric fever numbered 100, as compared with 44 in 1925. Among the 362 contacts examined bacteriologically five gave positive results. Two of these had had missed mild attacks; one was a true carrier who had had enteric fever 23 years ago; the fourth was a carrier detected in 1922; and the fifth was an example of a urinary type of carrier. He was admitted to hospital in April, 1926, and discharged after three negative specimens of urine and fæces had been obtained. After his discharge his mother and three brothers and one sister became infected, and *Bacillus typhosus* was found to have reappeared in his urine. Treatment with vaccines and antiseptics had little effect, and on Jan. 28th, 1927, he was admitted to Belvedere Hospital for special treatment. A small outbreak of diphtheria was traced to a carrier in the person of the proprietor of a dairy. He continued to be a carrier in spite of five months' treatment with antiseptics, after which a two months' course of treatment with detoxicated diphtheria vaccine appeared to be effective in rendering the swabs negative. There were 109 notifications of encephalitis lethargica, of which 43 were true cases. Only 20 out of the 43 actually sickened during 1926. The others were cases missed in the early stage, which were notified in order to gain admission to Stobhill Hospital, where some 60 beds have been set aside for post-encephalitis.

A case of anthrax occurred in Manchester about the beginning of April, and a case which proved fatal occurred in Glasgow on August 1st. Both were traced to shaving-brushes imported from Czechoslovakia. A considerable consignment of these brushes arrived in the country and was distributed in all directions. The shaving-brush was made of horsehair dyed to imitate badger, the handle being of white enamelled wood with a white label inscribed in red letters: "Guaranteed free from anthrax." The retail price was about 6*d*. The matter was reported to the Czechoslovak Consul. The first sample brushes examined in Prague gave negative results, but later ones proved positive, and stringent precautions were at once taken to prevent recurrence.

There were 25 notifications of trachoma, for which disease a special hospital ward is provided at Ruchill. During 1926 treatment by ultra-violet light was made available for the trachoma patients, and appears to give better results than have hitherto been obtained by operative methods, especially in the case of pannus of the cornea.

The question of dealing adequately with persons suffering from venereal diseases who refuse to undergo treatment is discussed in the report. A conference of the local authorities of Scotland was held in Glasgow in March, 1923, and Dr. Macgregor thinks that another representative meeting should be convened in order to consider whether a joint course of action can now be agreed upon.

The interlocutor and note of the sheriff with regard to the mosquitoes on Bogton Marsh are given in full.[2]

Aberdeen.

Dr. J. Parlane Kinloch shows that, in addition to the immunisation work against diphtheria and scarlet fever carried out by the staff of the health department, the medical practitioners of the city performed 1414 Schick tests and 1069 Dick tests. They immunised 1232 persons against diphtheria, 293 against scarlatina, and 1800 persons against combined diphtheria and scarlatina.

During 1926 44 cases of dysentery were notified, of which 27 were infections with the Sonne bacillus, 12 with the Flexner bacillus, 1 with both Sonne and Flexner bacilli, and 3 with cysts of *Entamœba histolytica*. In the remaining case the bacteriological examination gave a negative result. Evidence is accumulating which goes to show that summer diarrhœa in Aberdeen is due to the Sonne bacillus, and arrangements are in force by which cases will be largely removed to hospital with a view to further investigations of the relation of this disease to infection with the Sonne bacillus.

In the 1925 annual report an estimated need for 5000 new houses was indicated. A further comprehensive survey of the city's housing requirements made during 1926 shows that this estimate is, if anything, under the mark. The survey has also revealed the fact that 43 per cent. of the new houses are occupied by persons who have not released another house for occupation. The town council have authorised the building of 1000 dwellings in 250 blocks, each containing four three-roomed flats, as a first instalment towards the shortage. Only 25 per cent. of the patients with notified pulmonary tuberculosis were found to be occupying a separate bed in a separate room, and more than 50 per cent. had not a separate bed. At the end of the year 106 beds were on loan with bedding. The loaned beds and bedding are well cared for and nearly always returned in good and clean condition.

The chief cause of mortality among infants in 1926 was, as usual, prematurity, which accounted for 69 deaths, about three-quarters of them occurring within the first week. The second chief cause was respiratory diseases with 58 deaths. The total of infantile deaths was 328. Midwives attended about 20 per cent. of the confinements in the area, and sent for medical help in about 27 per cent. of their cases. There were 3406 births, and 1079 expectant mothers sought advice at the antenatal clinics. The dental and ophthalmic clinics are run jointly by the education and health committees. The marasmic ward at the city hospital admitted 170 infants chiefly suffering from nutritional disorders; 116 were improved, 22 died, and 32 were discharged at the request of the parents. During 1926 90 milk samples were examined for tubercle and 7 (or 7·8 per cent.) gave a positive result. There are now only 18 dairy herds in the city, the average number of cows being 197. The herds are inspected once a month.

During 1926 there were 36 notifications of puerperal fever with eight deaths, the figures for the preceding five years averaging 15 and 9 respectively.

Paisley.

Dr. G. V. T. McMichael reports that the usefulness of the isolation hospital is to be greatly increased by the provision of eight single-bed cubicles for the scarlet fever ward, two single-bed cubicles for the diphtheria ward, and an operating theatre adjoining the ward which is to be used for puerperal fever. He lays stress on the fact, however, that a new modern fever hospital should be provided on the outskirts of the town. Two-thirds of the 342 notified cases of acute primary and influenzal pneumonia were admitted to three hospitals. The case-mortality of the hospital cases was 27 per cent., while the case-mortality of the 158 cases treated at home was 48 per cent. The use of scarlet fever antitoxin in the isolation hospital appeared to cut short the acute stage in severe cases of scarlet fever, but did not seem to lessen the incidence of complications. Prophylactic doses were found useful in preventing cross-infection. New probationers are immunised, if found susceptible by the Dick test. Of the 54 notified cases of ophthalmia neonatorum 18 showed a gonococcal origin. There was no serious impairment of vision from this disease. During February and March measles was very prevalent; there were 1512 cases with 37 deaths, all except one under 5 years old. At the height of the epidemic all the health visitors assisted the epidemic nurse in the visitation of cases. The special provision for puerperal fever includes a ward at the hospital with

[2] See THE LANCET, June 25th, p. 1366, and July 9th, p. 81.

a specially qualified nurse in charge and the services of the consultant obstetric surgeon at the Barshaw Hospital for Women and Children. The attendances at the antenatal and child welfare clinics continue to increase. The provision for maternity cases at Barshaw Hospital has been increased from 18 beds to 30, and during 1926 the admissions to the antenatal wards numbered 122. The first attendances at the antenatal consultations numbered 278, and in addition 294 antenatal cases were seen at Barshaw Hospital. The total births were 1929.

The Russell Institute was formally opened by Princess Mary on March 19th, 1927, and serves as a central institution for all the various health services of the burgh. The domiciliary treatment of consumption is a special difficulty in Paisley owing to the high proportion of one- and two-apartment houses. The difficulty is only partially met by three local voluntary agencies, whose funds are available for helping cases of tuberculosis. Encouraging progress is being made with the various corporation housing schemes.

Dr. McMichael's estimateof the houses required to meet the needs of the district at the end of the year was 921.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 20TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 103 (last week 127); scarlet fever, 1236; diphtheria, 672; enteric fever, 96; pneumonia, 466; puerperal fever, 35; puerperal pyrexia, 90; cerebro-spinal fever, 4; acute poliomyelitis, 21; encephalitis lethargica, 31; dysentery, 13; and ophthalmia neonatorum, 109. No case of cholera, plague, or typhus fever was notified during the week.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 2 (1) from enteric fever, 19 (0) from measles, 8 (5) from scarlet fever, 13 (5) from whooping-cough, 13 (2) from diphtheria, 50 (8) from diarrhœa and enteritis under 2 years of age, and 21 (1) from influenza. The figures in parentheses are those for London itself.

NURSERY PROBLEMS.—A series of lectures on this subject will begin on Oct. 19th, at 3.15 P.M., at 117, Piccadilly, London, W. Among the lecturers will be Dr. Eric Pritchard, Dr. J. A. Hadfield, Dr. Crichton Miller, Dr. D. W. Winnicott, Prof. R. H. A. Plimmer, and Dr. Leonard Williams. Particulars may be had from Viscountess Erleigh, 65, Rutland-gate, S.W.

THE FABRIC OF ST. THOMAS'S HOSPITAL.—In his annual report Sir Arthur Stanley writes that "amongst the repairs executed during the year has been the rebuilding of all chimney stacks. It was found that these were showing signs of weakness, attributable to two main causes: (1) The deterioration of the mortar; (2) to the increasing vibration which is distinctly affecting the whole of the building. The greater part of the hospital is built on made-up ground reclaimed from the river bed when the Albert Embankment between Westminster Bridge and Lambeth Bridge was built. Great care was taken at that time to provide efficient concrete foundations, and it is impossible to conceive that these foundations could have been more efficiently laid; but the vibration caused by the weight and rapid pace of increasing traffic throws a severe test on buildings, however admirably they may have been built 50 years ago." The consulting architect states, however, that the building is structurally perfectly sound. The income of the Hospital last year was £156,555 and the total expenditure £176,199. For the next six and a half years St. Thomas's will receive from Mr. W. R. Morris a contribution of £16,000 per annum. The sum of £30,000, in part contributed by the trustees of the Rockefeller Foundation, and in part by the medical and surgical teaching staff, is available for the erection of an unit laboratory. During the year 11,243 patients were treated and the daily number of in-patients was 547.

POOR-LAW HOSPITALS.

To the Editor of THE LANCET.

SIR,—Your correspondents in THE LANCET o August 6th who took exception to the phras "professional degradation," applied by Mr. Hamilto Bailey—who is himself a surgeon to the Dudle Road (Birmingham Union) Hospital—to the posi tion of the Poor-law medical officer, have evidentl misunderstood his attitude. Far from attackin the staffs of Poor-law hospitals, Mr. Bailey's objec is obviously to raise their prestige and status. Ham pered for years by those unfortunate terms, "Poor law," "workhouse," our infirmaries and their staffs however efficient, have not received the recognitio which is their due either from the profession or th public at large. The only arbiters of professiona status, the profession and the public, do not recognis or appreciate at their full worth our infirmaries an their medical officers, and it follows that so far a prestige is concerned "professional degradation becomes, sooner or later, the unenviable lot of thos who staff these institutions. This attitude will cor tinue as long as the guardians hold administrativ qualifications as alone worthy of recognition an advancement, rather than executive professional ski and experience. The remedy is clear. The stigma o Poor-law must be removed from our infirmaries, an the members of the staff must be given free scop to exercise and prove their professional ability t their colleagues and to the public. To the professio apart from technical skill, teaching, research wor and literary output are the only recognised index o efficiency and status. Our infirmaries offer a vas but neglected, field for teaching purposes, in man directions more suited to this purpose than som voluntary hospitals. The material is there and th staffs are competent. Why are they not reco nised as teaching centres? Research work, again, not the monopoly of any hospital—*all* hospitals shoul make it their chief and glorious aim. Why not research encouraged, and why are not mo results forthcoming from amongst the unique an varied material at our large infirmaries? One reas is that research work entails systematic records, an that adequate encouragement and provision f keeping records is lacking at our infirmaries.

In order to increase the prestige of the medic officers of our infirmaries with the general public, th should be allowed and even encouraged to compe for and hold appointments upon the staffs (in speciali departments) of our voluntary hospitals. Also son opportunity for private practice should be permitte to the senior members of the staffs of our infirmarie in order that they may obtain the stimulus of healt competition and the reward of enterprise. Deni these incentives, they are likely to drift into th state where "what might have been" becom beyond their reach, and "professional degradation begins to set in. So true has this prognosis prov in a succession of brilliant medical officers at one our large infirmaries that the clerk to the guardia decided to devote his 25 years' experience a influence to counteract such happenings in t future, at any rate in the infirmary to which he attached. He had observed the initial enthusias keenness, and capability of a succession of m selected for this work in open competition wi other candidates, and had observed and lament that their early promise was not fulfilled. Aft repeated attempts to amend their conditions of wo his efforts were crowned with success. The medic officer of his infirmary was allowed as a tentati experiment (*a*) to compete for appointment upon t staff of the local county hospital (and in this he h been successful), (*b*) to use certain hours for priva

actice. The result has been so to enhance the iciency and status of the infirmary that a growing mber of patients ask to be sent there rather than the voluntary hospital, and this is not because y have to, or wish to, pay less for their treatment, t because they know that they will not only receive atment just as good, but also be charged a fair l reasonable weekly amount assessed in a business- e way upon their income. Of course, I am aware t all this is quite illegal (for they are not indigent sons), but it has to be done where long waiting s and shortage of accommodation at the voluntary spitals make any port in a storm necessary. peration on terms of equality between rate-aided l voluntary hospitals would solve the problem of iting lists and shortage of hospital accommodation. The problem concerns general practitioners very ply, for we are often hard put to it to find nursing ommodation and specialist treatment for the jority of our middle and lower middle-class people. ipers and capitalists alone can command these vices when needed. There is in fact an urgent growing need and demand for private wards clinics for those who can and will pay in proportion heir income. Insuperable difficulties seem to have herto precluded the voluntary hospitals from ering for such patients, though many of them are trying the experiment. Our infirmaries will haps sooner be able to provide this accommodation specialist treatment than our voluntary hospitals. ate-aided specialist service is already an established at the local infirmary to which I have referred, the British Medical Association has approved of scale of fees for specialist services agreed upon. at has been arranged for paupers can surely be nged for ratepayers. The clerk to the guardians whose foresight and initiative these advances are has, moreover, got out plans for private wards at local infirmary; the erection of a nurses' home set free for this purpose several wards in the n building now occupied by nurses.

ut the most important point of all in counter- ng professional degradation is a change in the ude of the guardians towards their medical ers. The present policy of the guardians is to out the most promising of their medical officers " promotion " and forthwith subordinate their essional skill, experience, and knowledge to inistrative duties. As medical superintendents become loaded with administrative work which ained business man could perform much better. the climax of this policy is reached when the of them all is appointed chief medical officer forthwith is submerged in a purely administrative —I am, Sir, yours faithfully,

ghton, August 25th, 1927. HENRY J. BAILEY.

THE SMOKING HABIT AND MENTAL EFFICIENCY.

To the Editor of THE LANCET.

R,—I have had an opportunity to make a new y of the smokers and non-smokers at Antioch ge this year as a control to the study which de in 1925, the results of which appeared in THE ET of May 22nd, 1926. This year the College ded me with a somewhat larger sample: 231 smokers and 215 smokers. The superiority of non-smokers in scholarship is as clear as it was e previous sample. However, the evidence which ared two years ago tending to incriminate ing as a *cause* of poorer scholarship is missing year. No decline in scholarship is evidenced by nokers who have been with us for the past three a. There is no significant difference between cholarship of smokers who inhale and those who t, nor between those who smoke much and those smoke little. It is true that during the year ave dismissed because of low scholarship 10·5 ent. of our heavy smokers, 6·7 per cent. of lighter ers, and only 2·5 per cent. of our non-smokers, and, since the grades of students who have been dismissed are necessarily excluded from our study, the remaining heavy smokers gain from these dismissals. Nevertheless, I feel that the results this year definitely weaken the case against tobacco as a cause of mental inefficiency.

May I repeat, to avoid misunderstanding, that there is no possible doubt of the association between low scholarship and the smoking habit, whatever the explanation may be?

I am, Sir, yours faithfully,

J. ROSSLYN EARP.

Antioch College, Yellow Springs, Ohio, August 17th, 1927.

CERTIFICATION OF THE INSANE.

To the Editor of THE LANCET.

SIR,—That this subject is one demanding the serious consideration of the profession, and apparently getting it, is proved by the important leading article in your issue of July 31st, and by your reports in the same issue and the subsequent one of recent discussions in Edinburgh. Unfortunately, no conclusions were reached at either of these discussions, for the speakers failed to agree on and recommend any one policy. This unsatisfactory state of affairs will, I fear, only defer the passing of any legislation, since until the profession knows its own mind the Legislature is not likely to move in the matter at all. The trend of opinion is, however, towards securing early treatment for insanity, and reducing to a minimum the legal enactments that only delay this early treatment. It is true that in Scotland such are less evident than they are in England, and yet Prof. Robertson maintains that no records of illegal detention exist there for the past 70 years; and we know that the evidence submitted to the recent Lunacy Commission satisfied them that it was practically unknown in English asylums. Therefore, if it is loss of liberty alone that concerns the legal world in this question the lawyers need no longer concern themselves with it, for in the treatment of this disease, in the large proportion of cases, " loss of liberty " is absolutely necessary, just as much as it is—temporarily, it is true—in the cases of administering an anæsthetic or extracting a tooth.

Again, under the present state of affairs, I am at a loss to see why it is the doctor, and not the magistrate, who is prosecuted in many cases; all the doctor does is to issue a medical certificate, the magistrate it is who signs an order for the patient's detention, and it is this order, not the doctor's certificate, that legalises the lunatic's detention. Some magistrates are so conscientious in the discharge of their duties that they refuse to sign any order unless, and until, they hold a court, *de lunatico inquirendo*, on their own, summon witnesses, take evidence upon oath, and generally delay the treatment of the patient, besides running up big legal charges. On the other hand, there are magistrates who, satisfied with the bona fides of the certifying practitioner, issue the necessary order without ever seeing the patient at all or taking any evidence.

It is thus seen how absurd is the calling in of the aid of the law before a medical man can satisfactorily treat this sad disease; and the cure is simple—divorce law from medicine altogether. It is true the lawyers would naturally object to any such plan, on the grounds that their relation has existed from times immemorial, but they have had their fling and it is now the doctors' turn. This divorce is the ideal at which we should aim, and if the B.M.A. make it their policy we should see a better state of affairs in this country than even exists in Scotland. All the legal elements that at present entangle the satisfactory treatment of insanity, and that select this only disease as the one to be " legalised," should be eliminated altogether—a medical certificate, and the consent of the Board of Control, being sufficient to empower the keeper of an asylum hospital to detain the person referred to " for care and treatment " until he is recovered, or

until the Board of Control makes other arrangements for his care.

It will be noted that I still consider the doctor's certificate an important document, and on it legal proceedings may be taken—no medical man can escape this risk. But I would suggest that such risks should be left open, as they are in other cases of carelessness or malpractice in medicine or in surgery. At present insanity is still looked upon almost as a crime, and it is because of this interference by the law in its treatment that the public cannot get over the feelings of shame and disgrace associated with this disease in any member of their family. To change the name of the disease, or the place of detention, is not going to reduce this disgrace—it is merely throwing dust in the eyes of the public. Until the profession has finally made up its mind, and our slow-moving legislature has evolved legislation—if such were still necessary—to simplify the treatment of the insane, the doctor will experience the same difficulties as have surrounded him in the past, and it will be a very serious matter if, as has been reported, a clause is being inserted in many partnership agreements prohibiting the certifying of lunatics. No general practitioner should certify an alleged lunatic unless he is prepared to state that the patient "is dangerous to himself or others." Unless this is so the patient cannot *legally* be declared of unsound mind, and unless a medical man can certify to this fact he should, if he would seriously consider his own future personal and financial safety, abstain from certifying. Only thus will he avoid possible litigation until the time comes when insanity is included among other diseases without the odium of legal red tape to hamper its early treatment.—I am, Sir, yours faithfully,

T. DUNCAN GREENLEES.

St. Leonards-on-Sea, August 19th, 1927.

CANCER AND ADRENALIN.

To the Editor of THE LANCET.

SIR,—The effect of adrenalin on transplanted animal tumours, recorded in THE LANCET of August 20th by Drs. T. Lumsden and J. G. Stevens, was described by me 22 years ago,[1] and the process of regression illustrated by two drawings. In my experiments the adrenalin was injected at a site remote from the tumour and not around the tumour, as in Lumsden's experiments, since a therapeutic agent which will act only on local application to a growth is obviously of little practical value. Subsequently Reicher[2] has reported the regression of transplanted tumours in rats and mice after the injection of adrenalin into the tissues surrounding the growth.

I am, Sir, yours faithfully,

W. CRAMER.

Imperial Cancer Research Fund, August 19th, 1927.

THE LABELLING OF EGGS.

To the Editor of THE LANCET.

SIR,—I was particularly interested in the communication from Dr. A. G. Everard, who apparently is a home egg producer of the better sort. I can assure him that medical officers of health generally would be only too pleased to carry out more active supervision of the eggs as supplied to the English consumer if the matter was not hedged about with so many difficulties. What is required, in my opinion, is a very simple legal enactment indeed, without any loopholes in the matter, but I fear this is too Utopian at the present time whilst there are such facilities for a certain class of English egg producers to fortify their home production by means of the imported variety.

I am, Sir, yours faithfully,

E. G. ANNIS,

August 19th, 1927. Medical Officer of Health, Greenwich.

[1] Second Scientific Report of the Imperial Cancer Research Fund, 1905, p. 60.

ASTHMA AND ARTHRITIS IN ALTERNATION

To the Editor of THE LANCET.

SIR,—It is a common observation that asthmat symptoms, in some patients, disappear during a intercurrent infection. This is the basis for th "protein shock" treatment of asthma. It would n therefore be surprising if asthmatic symptoms di appeared during the subacute phase of an infecti arthritis. The course of many cases of rheumato arthritis is not steadily progressive; remissions occu during which joint swellings, with pain and tenderne subside. It cannot therefore be unexpected that wh rheumatoid arthritis occurs in an asthmatic t symptoms of these two maladies may alternate. Dr Harold O. Long reports in your issue of August 20 a case of alternating rheumatoid arthritis and asthm and says he is on the track of an intestinal organis which he hopes is the cause of both conditions, a that a course of autogenous vaccines from this sour will arrest both conditions. The ætiology of the t disorders may be analogous. Asthma is genera recognised to be an allergic manifestation. I belie there is evidence that in rheumatoid arthritis t affected joints are sensitised to streptococci, and th the morbid process in the early stages of this conditi is one of "reactions" in such sensitive joints. B from the mere coexistence of asthma and arthritis c surely cannot conclude that the two maladies have t same essential cause.—I am, Sir, yours faithfully,

Harley-street, W., August 22nd. KENNETH STONE.

MEDICAL SCIENCE IN THE CITY OF YORK.—In a communication from Dr. G. A. Auden concerning e association of the City of York with the history of medic which appeared in THE LANCET of August 6th, "Dad de Bres" should read "David de Brus"—otherwise Dad Bruce, King of Scotland. Dr. Auden informs us that e earliest entry of a freeman barber-surgeon in the Roll Freemen is under the date 1299, and that this entry is follow by several hundred names of physicians, apothecars, surgeons, and barber-surgeons who received their freedo down to the latter half of the 18th century, when the list p lished by the Surtees Society was brought to an end.—ED.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—Dr. Reginald W. Statham has been elected Master of this Socie

At recent examinations the following candidates we successful in the undermentioned subjects:—

Surgery.—G. C. Rhys-Jones and E. H. Waller, Charing Cross Hosp.; and J. L. M. Wood, Sheffield.

Medicine.—L. J. Lawrie, London Hosp.; B. Rosenzt, Middlesex Hosp.; S. B. S. Smith, St. Bart.'s Hosp.; and V. R. Smith, Manchester.

Forensic Medicine.—K. E. Clark, Charing Cross Ho W. H. Collins, London Hosp.; F. W. Crossley-Holl St. Bart.'s Hosp.; T. C. Lansdale, Guy's Hosp.; J. Mi St. Bart.'s Hosp.; and V. R. Smith, Manchester.

Midwifery.—L. Ashkenza, Middlesex Hosp.; T. M. Bea Leeds; A. F. J. D'Arcy, St. Mary's Hosp.; J. Mi St. Bart.'s Hosp.; N. S. J. Roberts, Bristol and Ro Free Hosp.; and J. L. M. Wood, Sheffield.

The Diploma of the Society was granted to the follow candidates entitling them to practise medicine, surgery, midwifery: L. Ashkenza, T. M. Beattie, W. H. Collins, T. Lansdale, L. J. Lawrie, S. B. S. Smith, and E. H. Waller.

Medical Diary.

Information to be included in this column should reac us in proper form on Tuesday, and cannot appear if it rec us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 5th, to SATURDAY, Sept. 10th.—QUEEN MARY'S HOSPITAL for the East End, Stratford E. Post-graduate course in Medicine, Surgery, and the Specialties. Lectures and clinical demonstrations daily in all departments.—BETHLEM ROYAL HOSPITAL, St. George's Fields, S.E. Obituary.

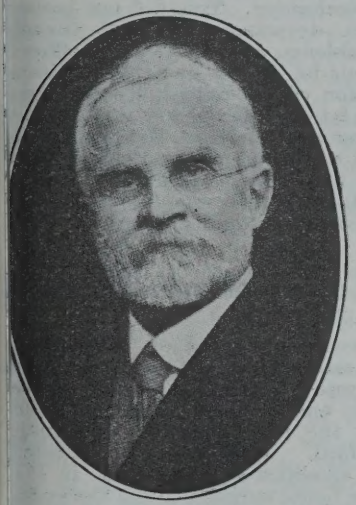
ALBAN HENRY GRIFFITHS DORAN, F.R.C.S. ENG.,

CONSULTING SURGEON TO THE SAMARITAN HOSPITAL.

As we announced briefly in the Students' Number ast week Mr. Alban Doran, the well-known natomist and gynæcologist, died on Tuesday, August 23rd, in St. Bartholomew's Hospital.

Alban Henry Griffiths Doran was the only son of ohn Doran, an Irishman, who came to London in onsequence of political troubles at the beginning of he nineteenth century. John Doran was a well-nown littérateur, classical scholar, and antiquary, nd was for a brief time editor of the *Athenæum*, ut is best known for his association with *Notes and ueries*, which he conducted with conspicuous success for many years. Alban Henry Griffiths Doran, his only son by Emma, daughter of Captain Gilbert, R.N., was influenced throughout his life by his father's love of letters, from whom he inherited the skill and grace which were the features of his considerable literary output, as well as untiring industry in research.



ALBAN DORAN, F.R.C.S.

Doran was born in 1849 in Pembroke-square, Kensington, and received his preliminary education at a school in arnes, entering the Medical School of St. Bartholoew's Hospital in his eighteenth year. He was a stinguished student, winning prizes with annual gularity, and on qualification as M.R.C.S., L.S.A., btained the resident posts and was afterwards ppointed demonstrator of anatomy in the medical hool. A year later he was appointed by the Royal llege of Surgeons of England anatomical assistant, s chief being Sir William Flower, who was Curator the College Museum from 1861 until he succeeded wen in 1884 as Director of the Natural History useum. Flower, both as Curator and later, in ccession to Huxley as Hunterian Professor at the llege, contributed greatly to the arranging and tension of the splendid anatomical preparations, d found in Doran an invaluable lieutenant. The llecting and setting in order of the materials quired for display led to the institution of a talogue of the pathological specimens in the useum, and in the compilation of this catalogue oran worked indefatigably with Sir James Paget d Sir James Goodhart.

Doran looked back on his youthful period in e Museum with great pleasure for it was then that made an intensive study of the ear bones of mmals, assembling and cataloguing for the College collection which is still regarded as a standard. e results of his inquiry into the anatomy and olution of the auditory ossicles formed an elaborate nograph which was published in the *Transactions* the Linnean Society, and in the evening of his life thing pleased him so much as a reference by a esent-day authority to his early monograph. Even he lay on what proved to be his death-bed his erest was at once aroused when a friend mentioned him that the accuracy of his description of the bones of the golden mole had been highly commended in a monograph just communicated to the Royal Society and thereafter he relapsed into the lament that there were two important gaps in his collection of auditory ossicles in the Museum of the College he had never succeeded in filling up. Such an instance is characteristic of Doran's attitude to the world; it was knowledge, not money, he thought of.

In 1875, while employed in the Museum, Doran took the Fellowship of the College, and shortly afterwards was elected assistant surgeon to the Samaritan Free Hospital. Here he came under the direct influence of Spencer Wells, who perhaps more than any one man can be called the originator of modern abdominal surgery. Wells was then at the top of his fame, having justified 20 years of assiduous work in perfecting his technique of ovariotomy, which operation was largely discredited by the medical profession when his enthusiasm and scientific skill re-established it as a life-saving procedure. It was no easy task to assist Spencer Wells, who was an extraordinarily careful operator and had progressed very far in operative success before the spread of Listerian doctrines made his technique, as applied to ovariotomy, the routine procedure over the whole field of abdominal surgery. Doran became well known in this department of surgery, and was attached to the Samaritan Hospital for over 30 years, and established there his claim to being a fine operator and an individual thinker. He never enjoyed a large practice, but he was always accepted, and rightly so, by the medical profession as a leading authority on his subject. He was an honorary Fellow of many European and American obstetrical and gynæcological societies, and was elected President of the Obstetrical Society of London in 1899.

Doran was not a voluminous author along professional lines. Apart from the note on the morphology of the ossicula auditûs, his only considerable contribution to medical literature was the "Handbook of Gynæcological Operations," which was published as far back as 1887. This work hardly obtained the reception which it deserved, and this may have been due to the difficulty in which reviewers were placed through its appearance at a time when there was a feeling that oöphorectomy was being performed with too great frequency, or at any rate that many of the questions in connexion with that operation, and with supravaginal hysterectomy, were the subject of discussion. Bantock, Wells, Knowsley Thornton, Keith in Edinburgh, and Lawson Tait had met with remarkable success here, but their followers, unaided by a proper understanding of antiseptics and without the individual skill of their masters, had brought operative gynæcology into some disrepute. Doran's book took no side in questions which were being anxiously asked. But it treated the surgical anatomy of the female organs with great care, and it is interesting to note, in view of the latest activity of the author's life, that several chapters were devoted to an account of instruments and appliances and their right use. Other sections summed up pathological appearances, explaining their significance and influence on diagnosis in the clear way that might have been expected from one who was a frequent speaker in the debates of the Pathological Society. The whole range of operative gynæcology was covered by accurate descriptions of the various procedures, and Doran was early in his distinct pronouncement that ovariotomy should be performed immediately the tumour is diagnosed, a view which few but Spencer Wells and his immediate disciples would have taken some years previously, but which had become tenable in consequence of the great reduction in mortality occurring after abdominal operations brought about by the discoveries and teachings of Lister. He was the first editor of the *Journal of Obstetrics and Gynæcology of the British Empire*, and his conduct of the enterprise during its first two years of life laid the foundation of after success.

Outside medicine Doran's pen was especially employed in the study of Shakespeare, and when he delivered the Annual Oration before the Medical

Society of London in 1889, he took Shakespeare as his subject. He was also interested in certain by-paths in English and French history, and it may be noted that his father had not only resided for many years on the Continent but was detained in France for three years as a prisoner during the Napoleonic wars.

Doran retired from practice about 18 years ago, and at once engaged in work in the Hunterian Museum. His first voluntary task was the revision of the extensive series of gynæcological specimens, for which he prepared a new descriptive catalogue—one which has been of the greatest use to all who consult this part of the Museum. His second task was the preparation of a descriptive catalogue of the great collection of obstetrical instruments presented to the College by the old Obstetrical Society upon its amalgamation with the Royal Society of Medicine. This undertaking involved Doran in a laborious and prolonged historical inquiry into the evolution of obstetrical instruments, and nowhere is his accuracy and breadth of scholarship so apparent as in this catalogue—in reality a text-book of reference. Having finished this task, he then proceeded to prepare a new catalogue—one for which there was great need—of the great collection of surgical instruments and appliances preserved in the Museum of the Royal College of Surgeons. Day after day he toiled at this task, which in the form of eight typewritten volumes was completed only two years ago. No one can write on the history of surgical instruments with profit without consulting this work, and it is to be hoped that means will yet be found for its publication. Eyesight and strength began to fail just as Doran brought this bold undertaking to an end, although latterly he was able to pay occasional visits to the Museum in order to catalogue additional gifts that had come in. It is pleasant to know that the work is being continued by Doran's friend, Mr. C. J. S. Thompson.

Alban Doran never married. After his father's death he lived for many years with his widowed mother in Granville-place, but since his retirement from practice, brought about by eye trouble, he had occupied a flat in West Kensington where he was for a long period under the care of Dr. Rickard Lloyd, who has sent us the following note: "In his declining years he used to discuss his growing afflictions with such courage and patience that he seemed to be considering the age, symptoms, and ailments of someone other than himself. While sight allowed he was a constant reader of current literature, although his especial interest was in medical news. Full of information, it was a great pleasure to hear him narrating his reminiscences of old friends and associations, and always showing notable affection for his old medical school and 'the College.'"

WILLIAM DIXON JEFFERSON, M.R.C.S. ENG., L.R.C.P. EDIN.

THE death of Dr. W. D. Jefferson took place at Ripon on August 22nd after an illness lasting some weeks. Born at Northallerton in 1855, he was the son of Mr. W. T. Jefferson, a solicitor, and went to Giggleswick School and later to King's College, London. He qualified as M.R.C.S. Eng. at the age of 22 and immediately settled at Ripon, taking over the practice of the late Dr. Frankland. For the last 50 years he had practised in the neighbourhood, holding the appointment of medical officer of health of the borough, besides being surgeon to the Ripon Cottage Hospital and medical officer to the first district of the Ripon Poor-law Union. This last post he resigned about a fortnight before his death. Dr. Jefferson was made an honorary associate of the Order of St. John of Jerusalem in recognition of his services in giving ambulance training to railway employees. He married in 1891 the daughter of the Rev. W. Gray, Vicar of Sharow. One of his two sons, Lieutenant Ingleby Jefferson, lost his life in the submarine service during the late war. The other holds a commission in the Welsh Guards.

ARTHUR DRURY, M.B. EDIN.

To the profession at large Dr. Arthur Drury, who died on August 22nd, at Halifax, was best known for his work as hon. secretary of the Jenner Society, as a president of the Association of Public Vaccinators of England and Wales, and as editor of the Jennerian supplement of the *Medical Officer*. Primarily, however, he was a Halifax practitioner, and nearly all his life was spent in his native town. As a boy he was a pupil at the Making Place School, Soyland, and though he continued his education at Edinburgh, where he took the first prize in mental diseases of the Royal College of Surgeons, he returned to Halifax soon after graduating in medicine in 1887, and took up practice in the neighbourhood. He was appointed medical officer of the Halifax Poor-law Union and public vaccinator for the borough, and in this last work found much to interest him, so that he became a keen advocate of vaccination, as well as an authority on its technique. This did not prevent him, however, from devoting time and thought to other medical problems, and apart from office in vaccinist organisations he was at one time chairman of the Halifax division of the British Medical Association. During the late war Dr. Drury was attached to St. Luke's War Memorial Hospital, Halifax, holding the rank of major in the Royal Army Medical Corps, and for some years he acted as medical adviser to the Halifax Rugby League. He was 65 years of age, and he leaves a widow, a son, and a daughter.

THOMAS PORTER GREENWOOD, M.R.C.S. ENG., L.R.C.P. EDIN.

Dr. T. P. Greenwood, who died on August 15th whilst leaving his house in answer to an urgent call had for many years enjoyed a large operating practice in South Lincolnshire and Rutland, and was medical officer of health to the rural districts surrounding the town of Stamford. Educated at University College, London, he qualified M.R.C.S. Eng. in 1875 and after a period as house surgeon to the Derbyshire General Infirmary went to Stamford Infirmary in the same capacity. He became assistant partner and successor of the late Dr. Row, and joined the surgical staff of several local hospitals, including the Stamford Infirmary and Browne's Hospital. Soon after settling in the district Dr. Greenwood was appointed medical officer of health, and he did excellent work in connexion with housing, scavenging, and the provision of hospital accommodation not only for Stamford but for the county of Rutland. He promoted the building of a small-pox hospital and of a maternity and children's ward at the Stamford Infirmary, and during the Rutland epidemic of poliomyelitis he placed a ward at the disposal of the authorities and was, as in other emergencies, unsparing of his time and labour.

"In the course of a long and successful career, writes a colleague," Greenwood acquired all that should accompany old age—honour, troops of friends, and the gratitude of innumerable patients whose lives he had saved or prolonged, or whose sufferings he had alleviated. But at three score years and ten he still preserved a keen interest in all medical matters. He was always eager to learn; new methods were carefully studied and easily acquired. As he was qualified as far back as 1875, it is doubtful if he could have seen much nose and throat work in his student days, but being keenly interested in this branch of work he became surgeon to the education authorities of the surrounding counties, and was almost invariably successful in the modern operation for the enucleation of tonsils and the removal of adenoids..... Indeed, his ready sympathy with the aspirations of modern public health work was one of his most remarkable traits. It has been said that no great man is a hero to his valet, but Dr. Greenwood was certainly one to his assistants. One of his old assistants advised his partner, who was migrating to Rutland, 'to call

reenwood when in difficulties, the best general actitioner in the Midlands.' What greater praise uld a man desire ? "

In 1903 and again in 1925 Dr. Greenwood was esident of the Midland Branch of the British edical Association. He died in his seventy-fourth ar, and leaves a widow and three daughters.

OLIVIER POLHILL TURNER, M.R.C.S. ENG., D.P.H.

GREAT regret is felt in Hastings at the death of r. O. P. Turner, deputy medical officer for the town, hich occurred on August 19th. He had been in poor alth for some time, but his death seems to have en hastened by going to help in the resuscitation of o people who had been rescued from the sea after bathing accident. Dr. Turner was a Londoner and idied medicine at University College. He qualified 1902, and after a house appointment at Brighton nt to Hastings some 20 years ago as school medical icer. Always a busy man, he was a prolific writer, d contributed a number of articles and letters to edical journals. During the late war he held a mmission as surgeon in the Royal Air Force, and ed as medical officer in the pathological department the Addington-park War Hospital, Croydon. He s a genial and generous man, and his somewhat erved manner did not prevent him from quickly king friends of those with whom he came in ntact. He leaves a widow and two sons.

HILIP FOSTER, M.D. ST. AND., M.R.C.S. ENG.

Dr. Philip Foster, who has died at Leeds at the a of 88, was the son of Dr. Edwin Foster, who ctised in the town for many years. He was icated at Leeds Grammar School and the Leeds hool of Medicine, and graduated as a doctor of dicine at St. Andrew's University when he was y 22, being the youngest holder of the degree at t time. With his brother, Dr. A. C. Foster, who rvives him, he had lived for many years in close rement at the house in Park-place which their ther had occupied before them. Dr. Foster's erest in medical and surgical science was conerable, and he published a number of works on hol, the maintenance of health, and similar ics. What brought him most to the notice of the fession in general was his report[1] of a case of Carean section in 1872. According to his account operation had only proved successful in six cases viously in this country, though it had been performed more than 60 times. Dr. Foster's comment this state of affairs was as follows: "Although results of operative procedure are thus shown to so terribly unfavourable, still to leave the patient nature, delivery being impossible through the ural passages, is to leave her to die. There is no ding, therefore, the responsibility of the operati ; and, if but one case in a thousand were successful, it would still be an imperative duty to urge to undertake it. I feel that the importance of *ating early* cannot be too strongly insisted n."

r. Philip Foster was a reader and writer of catholic e and sound judgment. He was especially well ed in the literature of Shakespeare, and some ye s ago wrote a series of 40 anniversary articles on Shakespeare in a Yorkshire newspaper. Starting practice in the days when a doctor made his rounds on horseback, he retained all his life a love of horses, breeding his own mounts both for professional work and hunting. He took a keen interest in racing, and is said to have seen the St. Leger run 65 times. His father, Dr. Edwin Foster, made a rule of never sending a bill for medical services, and his sons, we are informed, have generally followed this example.

[1] THE LANCET, 1872, i., 753.

FRANCIS BARTON, M.R.C.S., L.R.C.P.

THE death took place on August 14th, at Liverpool, of Dr. Francis Barton, who had been in practice for many years on Merseyside. He was a native of Woolwich, and was the fourth son of the late Colonel W. Barton, R.A. He came to Liverpool from the Channel Islands and received his medical education at University College, Liverpool, qualifying as M.R.C.S. Eng. in 1903. He began practice in Wallasey, but about 20 years ago he transferred to the Prince's-park district of Liverpool. He held several medical appointments, including that of medical officer of the Mersey Docks and Harbour Board, the Mercantile Marine Association, and the Rechabites. He was an active member of the Wesleyan community in Liverpool, a prominent Freemason, and a founder of the Liscard Temperance Lodge. He devoted a large part of his time to philanthropic work among the poor in the neighbourhood of Mill-street. Dr. Barton's wife died only a few months ago.

Appointments.

DUHIG, D. J., L.R.C.P. Edin., L.R.C.S. Edin., L.R.F.P.S. Glasg., has been appointed Honorary Assistant Surgeon to the Nose, Throat, and Ear Department, Dewsbury Infirmary.

Surgeons under the Factory and Workshop Acts: SIMPSON, C. B., M.R.C.S., L.R.C.P. Lond., for the Filey District, York, East Riding; WOOLLCOMBE, A., for the Okehampton District, Devon.

Medical Referee under the Workmen's Compensation Act: CAHILL, Lieut.-Colonel R. J., D.S.O., M.B., B.Ch., of Chester, to be an additional Medical Referee for the districts of the Chester and Nantwich and Crewe County Courts (Circuit No. 7).

Vacancies.

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road, E.—H.S.'s. At rate of £110.

Ayr County Hospital.—Sen. H.S. and Jun. H.S. At rate of £100 and £80 respectively.

Bath, Royal United Hospital.—H.P. and Asst. H.S. At rate of £120 and £100 respectively.

Birmingham City.—M.O.H. £1800.

Birmingham and Midland Eye Hospital.—Jun. H.S. £110.

Bristol Royal Infirmary.—Sen. Res. M.O. £200.

Cardiff City Mental Hospital, Whitchurch, nr. Cardiff.—Sen. Asst. M.O. £550.

Derbyshire Education Committee.—Asst. Sch. M.O. £600.

Devonport, Royal Albert Hospital and Eye Infirmary.—Asst. H.S. Also H.S. £150.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

Hastings County Borough.—Asst.M.O.H. and Asst.Sch. M.O. £600.

Hospital for Tropical Diseases, Endsleigh-gardens, N.W.—H.P. At rate of £110.

Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W. Res. H.P. At rate of £100.

Ipswich, East Suffolk and Ipswich Hospital.—Two H.S.'s and one H.P. Each at rate of £100.

Leeds Public Dispensary.—Hon. Dental Surg.

Leicester Royal Infirmary.—H.P. and H.S. Each at rate of £125.

Lister Institute of Preventive Medicine, S.W.—Research Fellowship in Bacteriology. £500.

London Hospital, E.—Surg. and Phys.

London Lock Hospital, 91, Dean-street, W.—H.S. At rate of £200. Also Surg. Reg. £100.

London Lock Hospital, Harrow-road, W.—H.S. At rate of £150.

Lord Mayor Treloar Cripples' Hospital, Alton and Hayling Island, Hants.—Asst. Res. M.O. £300.

Manchester, Ancoats Hospital.—H.S. At rate of £100.

Manchester Babies' Hospital, Burnage-lane, Levenshulme.—Res. M.O. At rate of £125. Also Jun. Res. M.O. At rate of £50.

Manchester Ear Hospital, Grosvenor-square, All Saints.—Non-Res. H.S. At rate of £150.

Manchester, Royal Children's Hospital, Pendlebury.—Res. Med. and Surg. O.'s. At rate of £125. Also O.-P. Dept., Gartside-street, Two Asst. M.O.'s. Each at rate of £150.

Manchester, St. Mary's Hospital, Whitworth-street.—Two H.S.'s. Each at rate of £50.

National Hospital for Dis. of Heart, Westmoreland-streeet, W.—Res. M.O. At rate of £150. Also Out-patient M.O. At rate of £125.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Res. M.O. £300.

Northampton General Hospital.—Two H.S.'s. Each at rate of £150.

Nottingham General Dispensary.—Res. Surg. £250.

Preston and County of Lancaster Royal Infirmary.—H.P. £190.

Queen's Hospital for Children, Hackney-road, E.—H.S. At rate of £100.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—H.S. At rate of £150.

St. Peter's Hospital for Stone, &c., Henrietta-street, W.C.—H.S. At rate of £75.

Salisbury General Infirmary.—H.S. £150.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Anæsthetist. £30.
Sheffield Royal Hospital.—Res. Anæsthetist. At rate of £80.
Tunbridge Wells Eye and Ear Hospital.—H.S. £150.
Warrington Infirmary and Dispensary.—Sen. H. S. £250.
West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each at rate of £100.
Westminster Hospital Medical School.—University Readership in Pathology. £800.
Whipp's Cross Hospital, Whipp's Cross-road, Leytonstone, E.—Res. Asst. M.O. £400.
Willesden General Hospital, Harlesden-road, N.W.—O.-P. Clin. Asst.
Williton Rural District, Somerset.—M.O.H. £110.
Wolverhampton and Midland Counties Eye Infirmary.—H.S. £200.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Stamford (Lincs.) and Llanelly (Carmarthen).

The Secretary of State for the Home Department gives notice that, in consequence of the death of Mr. W. J. Greer, L.R.C.P., F.R.C.S., one of the medical referees under the Workmen's Compensation Act, 1925, for the districts of the Chepstow, Newport, and Pontypool County Courts (Circuit No. 24), the appointment held by him is vacant. Applications (*from surgeons*) for the post should be addressed to the Private Secretary, Home Office, Whitehall, London, S.W. 1, and should reach him not later than Sept. 17th, 1927.

Births, Marriages, and Deaths.

BIRTHS.

BURNELL.—On August 17th, at Lemon-street, Truro, the wife of G. F. Burnell, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

NUNAN.—On August 21st, at Nairobi, the wife of Patrick Nunan, M.D., of a son.

WALKER.—On August 22nd, at Elgin-avenue, London, W., the wife of William Wood Walker, M.B., Ch.B. Aberd., of a daughter.

MARRIAGES.

FORBES—PENNY SNOOK.—On August 17th, at Holy Trinity Church, Weymouth, Dr. Colin Macphail Forbes to Helen Edith Mary Penny Snook, youngest daughter of Dr. and Mrs. Penny Snook, of Netherton House, Weymouth.

DEATHS.

BRADY.—On August 25th, of peritonitis, at Sydney, N.S.W., Andrew John Brady, L.R.C.S.Irel., L.R.C.P. Irel., and L.M.

CAMPION.—On August 23rd, at Cairo, Egypt, suddenly, from heart failure, Oliver St. Leger Campion, M.R.C.S. Eng., L.R.C.P. Lond., late Captain R.A.M.C., and Flight-Lieut. R.A.F., aged 35.

DORAN.—On August 23rd, Alban H. G. Doran, F.R.C.S. Eng., of Lisgar-terrace, W., aged 78.

DRURY.—On August 22nd, at Landon House, Halifax, Arthur Drury, M.B., C.M. Edin., aged 65 years.

GIBBES.—On August 25th, Cuthbert Chapman Gibbes, M.D. Aberd., C.M., M.R.C.P. Lond., D.P.H. Camb., of Oxford and Cambridge Mansions and Harley-street, aged 76.

HAWES.—On August 20th, at Abingdon-court, W., Francis B. Hawes, L.R.C.P. & S. Irel., aged 69.

JEFFERSON.—On August 22nd, at North House Ripon, William D. Jefferson, M.R.C.S. Eng., L.R.C.P. Edin.

LOW.—On August 29th, John Spencer Low, C.B.E., M.B., Ch.B., B.Sc. Edin., D.P.H. Lond., Barrister-at-law.

MCLACHLAN.—On August 21st, at Abbotsford-park, Edinburgh, John M. McLachlan, L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., late of Burbage, Leicestershire, in his 40th year.

PARSONS.—On August 21st, John E. H. Parsons, M.B.E., M.R.C.S., L.R.C.P. Lond., of Theobald House, Rochester.

TURNER.—On August 19th, of angina pectoris, at Marina, St. Leonards-on-Sea, Olivier P. Turner, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Oxf., Deputy Medical Officer of Health for the County Borough of Hastings, aged 57.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts

THE MEDICAL AFFINITIES OF G. P. R. JAMES.[1]

Mr. S. M. Ellis, who is well known for his writings Victorian writers, has followed up his study of Harris Ainsworth, G. P. R. James's contemporary and literary riv by a study of James himself. We confess that the impressi made upon ourselves by Mr. Ellis's account is that Jan was as mediocre as his books. By heredity he should ha been something more, for his grandfather was Dr. Rob James, the friend of Johnson, Garrick, Boswell, a Goldsmith, and the self-claimed inventor of the well-kno James's powders. As to the real composition of t preparation there is much diversity of opinion, but antimo was the chief ingredient, and antimonial powders were new thing in James's time, for so far back as 1587 Honourable Robert Dudley had invented the Pul Cornachinus, a mixture of diagridium, tartar, and diaphore antimony with cream of tartar. Dr. Robert James lef fortune of £8000 per annum, so in one way or another he highly successful. He was twice married, and by his secc wife had two daughters, one of whom witnessed all horrors of the French Revolution and had the doubt honour of being sought in marriage by Robespierre, and th sons, the youngest of whom, Pinkston, was the father G. P. R. James. Pinkston James in his youth served in navy, but about 1782 left the service and began to st medicine in Edinburgh. He married in 1791, and for ma years practised at 12, George-street, Hanover-squ where the future novelist was born at a date which variously stated as from 1799 to 1801. He appears to h entered the army, and it is stated that he was sent Waterloo, but his corps arrived too late to have any shar the actual battle. These things are stated on family evider but James could only have been about 15, an age which low even for a cornet or an ensign. After peace was decla James sojourned on the Continent and developed a consi able linguistic gift, wandering about France, Spain, Germany. He returned to England about 1825, and in 1 married Frances Thomas, daughter of Honoratus Le Thomas, who was twice President of the Royal Colleg Surgeons of England, although according to popular rep no great surgeon. After writing an astonishing numbe books, making a good deal of money, living in innumera different districts and houses, losing his money and continuing his hospitalities, James and his family departed New York, where they arrived in 1850. Here and in Bos he gave lectures, and after a short stay at Stockbridge Massachusetts, was appointed British Consul at Norf Virginia, a place of which his son, Charles James, giv dismal account. The climate, owing to the proximity of "Dismal Swamp," was unhealthy, malaria and yellow f abounded, and in 1855 there was a terrible epidemic of latter, the infection being apparently imported by American ship. It is intriguing to note that "the pestil was presaged in Norfolk by a plague of peculiar flying ins partly yellow in character," but epidemiology as a them fiction possessed no attractions for James, though ye fever in Massachusetts had evoked some 50 years be Brockden Brown's remarkable novel, "Arthur Merv In 1856 the consulate was removed from Norfol Richmond, whither James and his family removed, and the ill-luck which seemed to pursue them, met an epidem diphtheria, and James was attacked.

In 1858 James was appointed consul at Venice, and family left for Europe the same year. Charles Leigh Ja who was born in 1846, and had left England for Ameri the age of 4, has left an interesting account of his impres of London on his return to England, aged 12. Amongst things he notes of Regent and Oxford Streets: "T crossing at the Circus is the most crowded I ever anywhere. It is no unusual circumstance to have to 15 minutes for a chance to get over on foot." Of Ja short, somewhat happy-go-lucky career in Venice, unt death in 1860, Mr. Ellis gives an amusing account, as of Charles Lever, his brother novelist, who was cons Spezia.

Despite Mr. Ellis's efforts to establish a claim for J as a good novelist, we cannot go with him. It is true James's writings have been admired by Thackeray, Steve and Thomas Hardy, but to-day they have lost ap Scott, anyone over 50 can still read with pleasure, but vastly inferior is James's "Forest Days" to S

[1] The Solitary Horseman, or The Life and Adventu G. P. R. James. By S. M. Ellis. Kensington: The Cayme 1927. Pp. 303. 15s.

Ivanhoe." We would advise anybody who wishes to enjoy ames to-day to read not his own works, but Thackeray's Barbazure." Incidentally the Thackeray reference to hich Mr. Ellis alludes in a footnote on p. 267, and apparently nnot trace, is from "The Rose and the Ring." As an teresting and affectionate account of a writer who in his ay gave pleasure to thousands, Mr. Ellis's study is well orth reading.

THE REPORTING OF INQUESTS.

THE rider of the jury at a recent inquest reopens a subject eviously dealt with in THE LANCET on more than one casion, when we expressed the belief that the publication details was largely responsible for the great increase suicide from coal-gas. It is, we think, impossible to ntrovert this belief, and the views then expressed e strengthened by the remarks of the coroner and e jury's rider in the case under discussion. The roner, however, in telling the jury that the publicity the coroner's court was one of its greatest assets, and that had never sat *in camera* to the exclusion of the press, posed a situation in which publicity is obviously both an set and a danger. The aim of a coroner's court is to make own the facts concerning a particular death, and for that ason its procedure is less rigid than that of other courts, which the aim is justice as between one party and another. e public rightly demands that there shall be no secrecy ien a fellow citizen has died in circumstances other than ose attending ordinary processes of disease or decay; but satisfaction of this demand surely should be attained thout the unfortunate secondary results that so often ompany publicity. Legislation has stopped the publica- n of detailed divorce reports; they were recognised as pealing to unhealthy sentiments, though the evidence of m resulting from them was weaker than the evidence harm from detailed reports of inquests. The news value of uest reports is not based upon a legitimate demand for avoidance of secrecy, but upon unhealthy sentiments ich are pleasurably stimulated by such reading; and parently the pleasure does not diminish by the repetition the stimulus. The results of publishing the letters of cides are only part of an evil which undoubtedly leads an increase of suicide. It can be met by a better state public opinion, and, as suggested by Dr. Waldo, by the d influence and example of newspaper proprietors and tors.

FOLK-MEDICINE OF EXMOOR.

T is customary to write of primitives as though they sted only in the Australia of Spencer and Gillen, the zil of Spix and Martius, or in the South Sea Islands, enland, and Central Africa. But as a matter of fact the nitive is in our midst. He abounds even in London urbs, and is much to the fore wherever a remnant of ient peasantry lingers unconverted by education, or ier by progress. At the present day Exmoor Forest is largely a primitive stronghold, and there, more than in other English countryside, the old folk-medicine of our estors lingers among the elderly, however much they y deny the fact. Some half-century ago rational methods beliefs must indeed have been rare in this isolated on. Charms were universally employed, not only in rinary cases, where they are to be expected, but where nan beings were concerned. Mr. F. J. Snell, in his inating "Book of Exmoor" (Methuen and Co., 1903), tes the following as being still in vogue at the time wrote. It is a sovran charm to be used in cases of norrhage.

> "Christ was born in Bethlehem,
> Baptised in Jordan.
> The waters, wild and rude,
> The Child, mild and good,
> Put its foot into the flood,
> And bade it turn."

ciatica was, and indeed is, known by the admirably riptive term "boneshave," and the charm used to drive way is heathen in tone: "Boneshave right, boneshave ght, as the water runs by the stave [the line of willows the bank of a stream], so follow boneshave." The rer reclines in a damp situation by a riverside, and the m is repeated over him by a friend. However, rumour onest for once, and reports that a certain John Roden after undergoing the treatment. Another drastic edure, making for the survival of the robust, is prophy- ic, and consists of rubbing a baby all over with snow as as snow has fallen after its birth. This preserves nst chilblains in later life. A child with a congenital ia is passed through a cleft tree, a maiden ash that g possessed of peculiarly magical properties. This tment points back to pre-Christian paganism, even gh it be practised at sunrise on a Sunday. Mr. Snell knew a man whose brother had been thus radically cured. To prevent misconceptions the patient was willing to indicate the whereabouts of the tree. A child with whooping-cough was laid on the ground in a sheepfold. Goitre was cured by the touch of a corpse. Sufferers from lues were bidden adopt a signaturist treatment, and to wear the leg of a toad, torn from the live creature, in a bag round their necks. The wearing of a necklace made of borrowed silver coins was held to cure epilepsy in the course of a year. In the case of a girl epileptic a silver ring was substituted for a necklace or bracelet, and this had to be paid for by a tax on bachelors at the rate of a penny a head.

The seventh child of a seventh child was a born curer, and could touch for the King's Evil on Sundays. Such a one was sometimes christened "Doctor" or "Doctress." In a village churchyard near Bridgwater in Somerset there is a tombstone erected to the memory of Doctress Anne Pounsberry, "who departed this life Dec. 11, 1813, aged 73 years." "Stand still," continues her pious epitaph, "and consider the wondrous works of God."

The Evil Eye is known on Exmoor as elsewhere. Indeed, many of these beliefs and practices are universal; they seem to have become concentrated on this wild moorland in an especially well-developed form. It is to be hoped that some future psychologist or anthropologist will be moved to deal with primitive mentality in Western Europe, and especially in Ireland and the Celtic Fringe generally, in the manner of M. Lévy-Bruhl's classical works on the natives of different parts of the world. Such a work, for various reasons, seems still to be hanging fire. We need not go to taboo, mana, orenda, and other supernatural beliefs mentioned by Lévy-Bruhl, when we have their analogues, the "mascot" and "luck," constantly in our midst.

PEPSIN.

A METHOD of isolating the peptic enzyme directly from the gastric mucosa is described by F. Fenger and R. H. Andrew in the June number of the *Journal of Physiological Chemistry*. These workers dissect out the pepsin-producing glandular layers of pigs' stomachs a few minutes after death, clean and trim them in ice-cold water, allowing them to digest with acid water in a cold room overnight, and thus extract from the cells the native insoluble pepsin, partly as activated acid-pepsin and partly, as the hydrogen-ion concentration becomes less, as the enzyme itself. When the pH reaches 3·4 to 3·6 acetone is added in volume about equal to the total water-content. This admixture, while keeping the enzyme in solution, throws out mucin and leaves tissues undissolved. The addition of more acetone—about three times the water-content—very rapidly throws out the crude enzyme freed from more objectionable impurities. This pepsin dissolved in acidulated water may be precipitated by the addition of alkalis, but the authors prefer dialysis which introduces no new substances and reduces the acidity very gradually. At about pH 2·4 precipitation commences, going on until pH 3·85 is reached. From the examination of a series of specimens obtained by fractional dialysis, it is concluded that the purified enzyme is a nearly ash-free protein, quite insoluble in distilled water, but clearly and completely soluble in acidulated water. Its iso-electric zone lies between pH 2·4 and pH 3·85, the most active precipitates being separated at the higher hydrogen-ion concentration. The proteolytic activity of these ranged from 1 : 70,000 to 1 : 45,000 U.S.P. assay. The most active preparations were obtained in the autumn and the least active in spring.

The conclusion that the enzyme is a protein may be sound. It should, however, be pointed out that many other enzymes, assumed to be protein, have on purification ceased to give the characteristic reactions of proteins. Fenger and Andrew's process of cold digestion and extraction and subsequent dialysis doubtless tends to keep out of the preparation many products of hydrolysis which would be found in substantial amounts at higher temperatures.

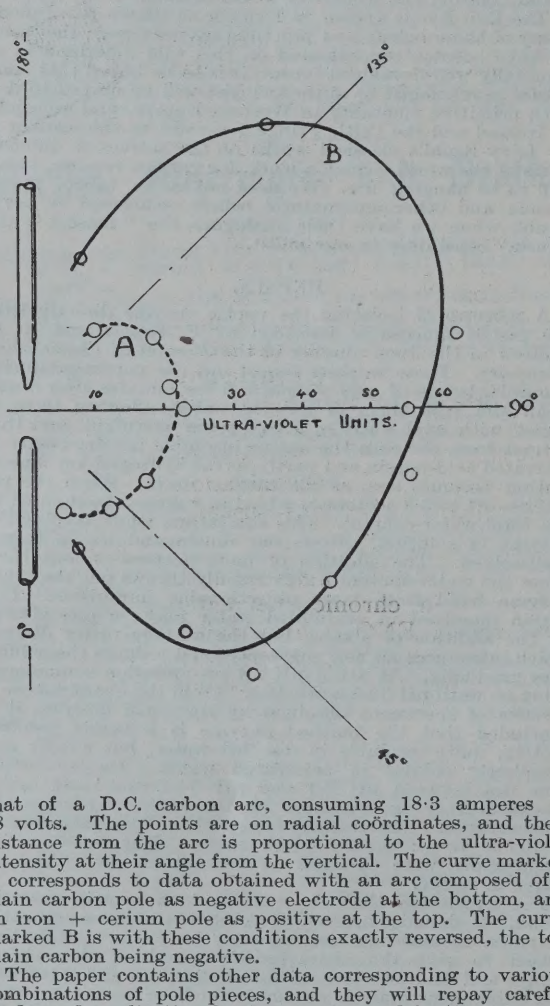
It will be interesting to see whether further work confirms the protein character attributed to the enzyme and justifies the conclusion of J. H. Northrop, which the authors "have found to be the true state of affairs," that "pepsin digestion is a chemical reaction in which the pepsin as well as the protein takes part . . . . the process . . . . is a progressive one in which the enzyme combines with other proteins and gradually loses its identity and physiological characteristics."

THE DESIGN OF THERAPEUTIC ARC LAMPS.

A PAPER by Mr. T. C. Angus, in the August number of the *British Journal of Actinotherapy*, will be read with interest by those who make use of carbon arc lamps for therapeutic purposes. Mr. Angus has made a series of measurements upon the erythema-producing rays emitted from a number of open arcs under various experimental conditions, and the results of these measurements afford valuable data affecting the economic running of these lamps. The rays

were measured by letting them pass into a Griffith & Taylor cadmium photo-electric cell,[1] having first passed through a filter of vitaglass to cut off the short wave-lengths. The ionisation current in the photo-electric cell served as a measure of the erythema-producing rays emitted by the lamp under different working conditions.

The carbon arc has long been used as a source of light, and when used for this purpose the top carbon of an arc is invariably made the positive or anode electrode, because most of the light comes from the crater at the end of the positive carbon. Makers of carbon arcs for therapeutic purposes have followed this example in construction, but Mr. Angus shows that a considerable increase in ultra-violet radiation occurs when the bottom carbon is made the positive electrode. This observation was first made by means of measurements upon the horizontal intensity, but the author has also carried out a long series of tests in other directions, and the main results can be seen from the accompanying diagram taken from his paper. The case illustrated is



that of a D.C. carbon arc, consuming 18·3 amperes at 78 volts. The points are on radial coördinates, and their distance from the arc is proportional to the ultra-violet intensity at their angle from the vertical. The curve marked A corresponds to data obtained with an arc composed of a plain carbon pole as negative electrode at the bottom, and an iron + cerium pole as positive at the top. The curve marked B is with these conditions exactly reversed, the top plain carbon being negative.

The paper contains other data corresponding to various combinations of pole pieces, and they will repay careful study and application by those concerned in the economy of these sources of ultra-violet radiation.

THE PATHOLOGY OF BLUSHING.

BLUSHING, as Darwin wrote, is the most human of all the expressions of human emotion, for in normal people it signifies an awakening of feeling in those regions of the mind which in ordinary superficial social intercourse lie beyond a barrier. There are, however, people who blush on the slightest provocation, and who suffer so much distress from this disability that they urgently demand relief.

In a recent article (August 13th, p. 1003) in the *Presse Médicale*, Dr. P. Hartenberg outlines a theory of the causation of blushing and suggests a remedy. A person becomes an "ereuthophobe," he says, (1) because he blushes excessively, (2) because he is of an anxiety-type. He concludes from his observations of the malady that its organic basis is an abnormal condition of the heart and the vessels, particularly those of the head. The heart is excitable, wit an exaggerated impulse but no acceleration of rhythm the carotid arteries are sensibly dilated and their pulsatio is visible as well as palpable. These pulsations extend t the arteries of the head and face. Blushers suffer also from feeling as of hot gusts in the head and from profuse perspira tion; their blood-pressure is apt to be low, and they ofte have dermatographic skin. They are the victims of a co titutional imbalance between their vaso-constrictor an vaso-dilator systems, the latter predominating. The blushing is not confined to emotional crises, but follows heavy meal, a rapid change from cold to warmth, or th act of lying down. It is essentially a physiological ailmen and by no means all blushers are neurotic. Ereuthophobi he describes as the combination of the blush-syndrom with an anxiety neurosis, and the combination is a ver formidable one, for the fear makes the blushing wors and a vicious circle is formed which soon becomes a co ditioned reflex. Dr. Hartenberg proposes to treat th physiological blushing, first, by eliminating heavy meal hot rooms, alcohol, and all other physical causes of vas dilatation; and by forbidding all but a minimum intake fluid until the volume of the blood is reduced. The dilatatio itself is counteracted by daily doses of quinine, ergot adrenalin. For the anxiety state he recommends sedativ and warm baths. He claims that under this régime th abnormal activity of the heart soon abates, with all i symptoms, and that the tendency to blush is broug within reasonable bounds; this has a powerful effe on the patient's psychological state, and, finding tha he is no longer blushing as he did, he gains confiden and freedom.

NATIONAL INSTITUTE FOR THE BLIND.

THE annual report of the National Institute for the Blin 1926–27 (headquarters, 224–28, Great Portland-stree London, W. 1), is an exhaustive account of the work of t largest institution for the blind and the largest publisher embossed books in the world. Last year nearly 20,0 bound volumes were issued in Braille type, and the numb of pamphlets, magazines, and newspapers exceeded 300,00 In addition, about one-fifth of these numbers were issued Moon type, a modified Roman type adapted for the use those who become blind late in life. The books are not novels, but include educative works of all kinds. T average cost price of a volume is 8*s*., but a discount of tw thirds of the cost price is allowed to all blind purchase throughout the British Empire, and copies of all publicatio are presented gratis to the National Library for the Bli for free circulation among blind readers. Taking into co sideration these and other concessions, the approxima amount needed to keep the Braille and Moon producti up to its present standard is £12,000 per annum. One the most popular of the periodicals is the *Braille Rac Times*, produced with the coöperation of the B.B.C., w broadcasted an appeal for funds sufficient to enable t Institute to purchase the necessary additional plant. T circulation of this periodical already amounts to 1500 copi a fact which is some indication of the boon that wireless proving to the blind. A scheme was initiated by the Institu last year providing for the reconstruction of its council a more representative basis, and empowering it to op negotiations with local voluntary agencies with a view framing collecting agreements. This scheme shou minimise overlapping in either administrative or colle ing activities; arrangements with 37 local agencies ha already been concluded, while many more are under co sideration.

The Institute's Home Industries Committee is concern with the welfare of blind home workers in the metropolit district south of the Thames and in the counties of Ke Surrey, Sussex, and Hampshire. At present there 184 blind men and women who come within the scope this organisation, by which the expense of the middlem in obtaining raw material and marketing the finished goo is eliminated, and the workers are helped in various oth ways. Through the Institute's Appointments Board further number of blind workers have been placed factories ordinarily employing only sighted labour. About are engaged as telephonists throughout England and Wal but the majority of the workers trained under the auspi of the Institute are engaged in the profession of massa Twenty years ago the average wage earned by the bli was somewhere about 15*s*. per week. Last year the aver payment made per week to blind men was £2 3*s*. 2*d*., a to blind women £1 15*s*. 4*d*. Among other undertakings which the Institute is directly responsible are the Chor Wood College for Blind Girls, three Sunshine Homes Blind Babies, homes and hostels for blind women, and management of the Greater London Fund, which assi all the leading metropolitan workshops and societies the blind.

Experimental Researches
ON THE
NATURE OF THE BACTERIOPHAGE.

Lecture given in the Institute of Pathology and Research, St. Mary's Hospital, London, on May 5th, 1927,

BY DR. CARL PRAUSNITZ,
PROFESSOR OF BACTERIOLOGY AND HYGIENE IN THE UNIVERSITY OF BRESLAU.

THE first conclusive observation on the phenomenon of transmissible lysis in bacteria was made by Twort: that cocci obtained from glycerinated small-pox vaccine, when grown on agar, occasionally showed peculiar malformations of their colonies, which appeared as if gnawed away at the periphery by some foreign agent; and that by using filtrates of such cultures the malformation was produced at will in colonies of hitherto normal cocci. The second fundamental observations we owe to d'Herelle.

D'HERELLE'S OBSERVATIONS AND VIEWS.

It had for long been remarked that it is often impossible in dysentery patients to cultivate the usual micro-organism although, when once obtained, it grows well on ordinary laboratory media. D'Herelle assumed that in the intestine of such patients there must be present a substance harmful to the dysentery bacillus. In order to prove its existence, he passed emulsions of dysenteric stools through bacterial filters; the filtrate, free from micro-organisms visible or cultivable, when added to fresh broth cultures of the dysentery bacillus, not only inhibited their growth, but in a few hours completely dissolved them, leaving the broth absolutely limpid and sterile, as if no bacteria had ever been in it. The next advance in his research was made, when he found that addition of a small quantity of this limpid fluid to a fresh broth culture of dysentery bacilli brought about the same clarification and that the process could be repeated at will in subsequent passages. The clarifying power of the fluid increased from passage to passage, until it reached its maximum—at this stage it is as a rule active to a thousand millionfold dilution.

Further experiments were carried out with solid media. The mixtures of the cleared fluid with bacterial emulsion were spread over the surface of agar. When large quantities of the fluid were employed, the agar remained completely sterile; if the quantity was reduced, irregular isles of bacterial growth developed on the agar surface; on still further reduction of the fluid a uniform growth of bacteria was obtained, interrupted only here and there by circular spots or areas denuded of bacterial growth; the number of these clear areas was shown to be directly proportional to the quantity of the clear fluid added to the bacterial emulsion. It was thus proved that the agent producing this bacterial lysis was capable of endless reproduction in living bacterial cultures, that it was *enhanced* in its dissolving power by repeated passage through such living bacteria, and that it was a *particulate* substance; for otherwise the occurrence of the isolated lytic areas on the agar surface could not be satisfactorily explained.

The facts observed were explained by d'Herelle as due to a living micro-organism, minute in size as compared with the bacteria attacked, a filterable ultra-virus which he named the bacteriophage.

THE BACTERIOPHAGE.

Further researches showed that as a rule multiplication of the bacteriophage takes place only so long as the bacteria are actively proliferating. As yet it has not been possible to obtain any multiplication of the phage on killed bacteria. One step in this direction has, however, been made by Twort, who showed that a mixture of dead and living bacteria with the phage could under certain instances be completely dissolved, thus proving that under favourable circumstances even dead bacteria were attacked and dissolved by the phage. This has been confirmed by Bronfenbrenner and Muckenfuss.

The phage is specific to a certain extent. Some dysentery phages act only on certain strains of dysentery bacilli; on the other hand, many phages act on quite a number of other bacteria—e.g., a dysentery phage may dissolve not only Flexner, Shiga, Hiss-Russell, and Strong bacilli, but also typhoid, paratyphoid, coli, staphylococci, &c. Usually, however, a phage is primarily active only against one species of bacteria, although its "virulence" may be enhanced for other bacterial species by repeated passage through their cultures. Phages have been obtained from a large number of bacteria—e.g., plague, hæmorrhagic septicæmia, pyocyaneus, cocci. For a long time it was difficult to obtain a cholera bacteriophage, but Miss Meissner and I found a simple method, by intraperitoneal injection of sterile broth in guinea-pigs, of proving the presence of the phage in the normal guinea-pig.

Phages are normally present in the intestines of many animals, and also in fæcally polluted rivers, lakes, and sea-water. In the human intestine they are not often found, as was proved by me and Van der Reis on examining a large number of diseased and healthy persons with his intestinal cartridge method.

Bordet showed that animals can be *immunised* against the bacteriophage by repeated injections. With a serum thus obtained I found that the neutralisation of the phage by its corresponding antibacteriophage serum follows the "law of multiples" formulated by Ehrlich—i.e., if a given quantity of phage is rendered inert by a certain amount of the specific serum, then a multiple of the phage is rendered inert by the corresponding multiple of the serum.

Many disinfectants destroy the phage, yet on the whole their concentration and time of action must be considerably greater than is required for the destruction of most bacteria; it approximates more closely to that required for tubercle and spore-bearing bacteria. Lastly, the interesting fact has been demonstrated that in contact with a weak phage, the corresponding bacteria may become refractory to its action—i.e., they may lose their capacity of being killed and dissolved by the phage; this resistance towards the phage is hereditary to a certain extent and is very strictly specific (Bail).

The question of primary interest deals with the *nature* of the bacteriophage. D'Herelle's original view that it was a filterable virus has been much debated, and a number of different and contradictory hypotheses have been enunciated; these may be collected under the following main headings: (1) The phage is derived from the bacterium; it might be a bacterial fragment (Bail) or an autolytic ferment (Kabeshima). (2) The phage is derived from the host (Bordet). (3) A further suggestion, first made by Doerr, and elaborated by Eastwood, is that the bacteriophage action is due to an excess of the hormones which in their normal concentration stimulate bacterial growth; thus, the balance between assimilation and dissimilation would be removed in favour of the latter.

(1) IS THE PHAGE DERIVED FROM THE BACTERIAL CELL?

This view is shared by numerous authors who have succeeded in isolating phages from old laboratory stock strains of bacteria showing no outward signs of bacteriophagy. D'Herelle was the first to explain this observation by the assumption of "mixed cultures." In fact, knowing that the phage is found more or less regularly in the intestinal contents, and occasionally in other parts of the normal and diseased body, it is easily understood that bacteria isolated from man or animals may be contaminated with the phage; if the phage is weak, the bacteria may rapidly become refractory; in subcultures the bacteria will be propagated alongside of the phage indefinitely, the more so because it has been shown that in a culture of refractory bacteria there are always present some individuals less resistant, which will serve for the propagation of the phage. This explanation is particularly borne out by the careful experiments of Flu, who from such cultures succeeded in obtaining the bacteria "ultra-pure,"—i.e., free from the phage—and in subculturing these ultra-pure strains indefinitely without a phage reappearing in them. Still,

this view is strenuously opposed by numerous investigators, according to whose view, the bacteriophage is always derived from the bacterium. Two explanations are chiefly given for the supposed bacterial origin of the bacteriophage.

(*a*) According to Bail, bacteriophagal action is due to the formation of minute (filter-passing) fragments from the bacterial cells; these, on addition to normal bacteria, should attract and absorb a part of their nutritive substance, in the endeavour to attain the normal bacterial size and form. This must lead to the destruction of the bacteria deprived of part of their nutritive substance, and in this process fragmentation would occur afresh, and so on. This hypothesis would seem to be akin to the modern work of the French school on filterable forms of certain pathogenic bacteria, particularly the tubercle bacillus. However, I wish to emphasise that this "vampyre-theory" is open to several objections; chief of these is the following fact, found by Wollmann, Otto, and myself. A broth filtrate containing the phage needs must also contain dissolved products of the corresponding bacteria. If now animals are immunised against such bacteriophage broth, their serum is found to possess substances antagonistic both to the phage (antibacteriophage substances), and to the bacterium (agglutinins, complement-binding substances). If such a serum is treated with emulsions of the bacteria (technique of Castellani), it can be completely deprived of its antibacterial power, but its anti-bacteriophage titre remains absolutely unchanged. To my mind, this is proof positive that the substance of the phage is chemically distinct from that of the corresponding bacterium.

Further facts have been brought out in absorption tests carried out by Gildemeister. Alkaline colloids (oxide of alumina) do not absorb it at all, neutral colloids (blood coal) slightly, but *acid* colloids (oxide of silica, kieselgur) very strongly; a phage filtrate, shaken with SiO_2, may lose its lytic power completely; but from the absorbate the phage can be partially recovered by treatment with weak alkali (n/30 or n/100 ammonia). It would thus appear to be *electropositive*. This is corroborated by a research carried out in my Institute by Karl Koch, which showed that under the influence of a weak electric current under a potential of 100 volts the phage undergoes cataphoresis and wanders towards the cathode. Experiments on the electric charge of the bacteria have not given uniform results, but it is worthy of note that some authors consider them to be electropositive. On the other hand, Bechhold has recently shown certain ferments to be electronegative.

(*b*) A different view from that of Bail was first pronounced by Kabeshima. According to him, bacteriophage action is merely a special case of fermentative autolysis, a phenomenon long known to occur in many bacterial cultures. With this hypothesis the phage would be a catalyser, which, on addition to certain bacteria, activates the pro-ferment of the autolytic ferment normally contained in them; the bacteria undergo dissolution, whereupon the catalyser again becomes free and activates the pro-ferment of other bacteria in the culture, and so on, until the available bacteria have all become dissolved. On the face of it, this hypothesis would seem very plausible, but one objection at once arises, it is a question of *quantity*. It has been indicated that from a small, almost infinitesimal amount of the phage one can obtain, by repeated passages in broth-cultures of the corresponding bacterium, any amount of the phage; if now the catalyser is an "outside" substance, this would not seem feasible. One would have to make the further assumption that the catalyser was also derived from the bacteria. But if both catalyser and pro-ferment are contained in the bacteria, then why are the bacteria not always and normally dissolved? Obviously, one would have to imagine a further hypothetic substance, a "catalyser to the catalyser," and thus there would be no end to these complications, we find ourselves reduced *ad absurdum*. Apart from this objection, however, the ferment hypothesis of bacteriophagy fits in well with several other facts, as will be shown further on.

(2) IS THE PHAGE DERIVED FROM THE HUMAN (O ANIMAL) HOST?

Bacteriophagy is a disease of the bacteria, inherite from generation to generation. Is this disease a infective or a constitutional one? Bordet believe the disease to originate from antagonistic substance of the host, possibly of leucocytic origin; his theor is briefly summed up in the name given by him t the phenomenon: "hereditary nutritive vitiatio of the bacteria." Thus fermentative processes i the host would induce an abnormal metabolism c the bacteria; the more rapidly the bacteria grov the more speedily would they be broken down an dissolved. Nothing is more natural than that suc a disease should be inherited continuously i organisms like bacteria, which are incapable of repair ing the constitution of their germinal plasma by sexu proliferation.

It has been stated by Borchardt that bacteriophag can be set going by adding trypsin, activated by enterokinas to the bacteria; but these experiments have not bee satisfactorily reproduced by others. Besides, they are n conclusive, because it is often possible to obtain the phag from the normal body, but this is far easier with filtrates c the intestinal contents than with those from the pancreas.

Still, it must be admitted that certain facts favou an hypothesis which views the phage as an inanimat ferment. Chiefly in favour of such hypothesis are th following facts:—

(*a*) The fact above mentioned, that the phage can l almost quantitatively adsorbed by certain colloids, at fir sight appears more easily explicable by the ferment hypothes than by the supposition that the phage is a living organisn But quite recently Bechhold has showed that from broth culture of bacteria 99 per cent. of the microbes ca be removed by shaking with an electronegative colloi (oxide of silica).

(*b*) It has been mentioned before that an immune seru neutralises the bacteriophage according to the "law c multiples." These relations are known to occur regularl between toxins and antitoxins, also between ferments an antiferments; but we know of no case where a microl or its endotoxins are destroyed by the corresponding immur serum according to this law. Besides, so far as we knov such destruction is only effected by a serum in the activ state—i.e., in the presence of *complement*; but the bacteri phage is neutralised equally well by an inactivated seru (after heating for half an hour to 56° C.) as by the same seru in its active state. Thus the supposition that the phage a living being is only tenable if we make the further assum tion that its destructive action on the bacteria is the resu of ferments carried or secreted by the phage.

The oft-quoted fact that disinfectants destroy th bacteriophage is explicable equally well by th ferment hypothesis as by that of d'Herelle, fc all ferments are more or less injured by treatmer with disinfectants. In spite of the objections he stated, a certain number of investigators, to whom also belong, believe d'Herelle's view to be the corre one.

IS THE BACTERIOPHAGE A LIVING ULTRA-MICROBE

The case for the ultra-microbe is not an easy on as has been shown. How is one to prove the life c something no one has ever seen? Particulate w must assume it to be, for otherwise it is hardly possibl to explain the formation of separate, localised area denuded of bacterial growth in thinly-seeded age cultures, nor the proportionality of these areas t the concentration of the phage.

My first endeavour was to estimate the *size* of th phage corpuscles. To this end, membrane filters c graded permeability were employed, as furnished b the firm de Haen in Göttingen. The membrane are a fraction of a millimetre in thickness and hav an absolutely smooth surface; thus their powe of absorption, as was shown in control experiments is extremely low, so that a reduction of the strengt of the phage when filtered through these membrane must be attributed not to absorption, but solel to the relation between the size of the pores and th diameter of the phage corpuscles. Whilst the fines

ilters retained the phage, and the most porous ones et it pass almost without loss, a certain intermediate grade reduced the power of the phage considerably. Bechhold gives the following sequence of size of colloidal substances :—

Collargol 20 μμ.
Colloidal gold 1–4 μμ.
1 per cent. gelatin solution.
1 per cent. hæmoglobin solution (mol. weight about 16,000).
Serum albumin (mol. weight 5000 to 15,000).

In my experiments the filters which partially rrested the phage also arrested collargol in about he same proportion, whilst allowing the practically nreduced passage of 1 per cent. gelatin solution, per cent. hæmoglobin solution and serum albumin, s well as of pepsine, trypsin, and an invertase rom yeast cells. It therefore seems permissible o estimate the size of the phage corpuscle to be omewhere near that of collargol—i.e., 20 μμ. There good reason for believing that the micro-organisms f pathogenic filterable virus are considerably above nis dimension, and only slightly below the limit of ur vision; their diameter is probably between 00 and 200 μμ. *Is it possible to imagine particles of nly 20 μμ to be endowed with life?*

The mass of a phage particle of 20 μμ diameter would e, assuming its density = 1, $\frac{4}{3}\pi.10^{-18}$ g. In order to timate how many proteid molecules such a mass could ntain, it shall be assumed that each molecule, presumably roteid, must contain at least 1 atom of sulphur. This eighs approximately 10^{-24} g. The amount of sulphur in acteria has been found to be 1/100 per cent. If the chemical mposition of the phage were similar, then one phage rpuscle would contain $\frac{4}{3}\pi.10^{-22}$ g. of sulphur and this ould represent about 400 atoms of sulphur; thus it may e deduced that one phage corpuscle contains about 400 olecules of proteid matter. Can so minute a body be edited with the complex manifestations of life?

The chief of these manifestations—metabolism and oliferation—will not help us in the decision of is difficult question: metabolism cannot be proved exist, since in bacteriophagal multiplication there always simultaneously present the proliferation of e bacteria; proliferation, or what appears to be oliferation, is therefore accounted for by the ferment pothesis as well as by the assumption that the iage is something living. But there still remain two atures which, so far as is known, are absolutely aracteristic of living bodies: random variability, correctly called "mutation," and variability in definite direction—e.g., in overcoming noxious fluences, "modification" or adaptability. It has en my main object to demonstrate both of these atures in the phage.

(*a*) *Random Variability.*—From an agar plate lture presenting some distinct bacteriophagal clear eas, different areas are subcultured in tubes of oth, which have been seeded with equal numbers of cteria; the tubes are incubated for 24 hours at ° C., then filtered through bacterial filters. As a le, the different subfiltrates, although derived parently from one original phage strain, show arked differences in their behaviour towards anti-cteriophage serum and towards disinfectants.

The neutralisation by the antiserum is measured as llows: into each one of a series of sterile test-tubes we 1 c.cm. of a freshly prepared emulsion of bacteria in broth, c.cm. to contain about 250,000,000 bacteria). To one of ese tubes we add 0·2 c.cm. of a mixture of equal parts of the age and its antiserum in thousandfold dilution with normal ine and mix thoroughly; to a second tube also containing .cm. of the bacterial emulsion we add 0·2 c.cm. of a mixture equal parts of the phage and normal saline; thus the latter be serves as control to the former. From each of the two xtures we withdraw with a calibrated capillary 0·1c.cm., w it out on to the surface of a fresh agar plate, spread roughly over the surface with a glass spatula, and ubate for 24 hours at 37° C. The number of clear ar the bacterial growth on these plates indicates the num of viable or active phage corpuscles. Since the antibacteriophage serum neutralises at least part of the phages in the first mixture, the number of areas developing in the culture inoculated from the phage antiserum mixture must be smaller than that in the control; the ratio of these two figures indicates the titre of the antiserum.

If, now, we had originally subcultured not only one area, but several, always working under exactly the same conditions with broth and agar of the same date of making, then we find the titre to show marked, sometimes very pronounced, differences for the different substrains of phage. Similarly, this difference is at least equally marked, if we treat the phage not with antiserum, but with some disinfectant, the technique otherwise being the same.

(*b*) *Variability in a Definite Direction.*—It is a well-known fact that bacteria can be accustomed, by repeated passages through weak concentrations of certain disinfectants, to grow in the presence of concentrations of this disinfectant, which at the outset would have killed them—e.g., *B. coli* in phenol. It was my aim in like manner to accustom the bacteriophage to disinfectants. Thus, mixtures of equal parts of a phage and of sublimate solution 1 : 10,000 were kept at room temperature in the dark for a day, then seeded on an emulsion of 250 million bacteria per c.cm. of broth and spread on the surface of an agar plate as described before. Some of the clear areas developing on the agar were picked off, inoculated into fresh bacterial broth culture, incubated, and after complete lysis had occurred, were filtered. The strains of phage thus obtained may be called "sublimate passage strains"; of each of these one part was again mixed with equal parts of sublimate 1 : 10,000, another part, serving as control, was similarly diluted with normal saline. The mixtures were kept in the dark at room temperature for a day; then from each of them 0·1 c.cm. was transferred to 1 c.cm. of fresh bacterial broth emulsion, and 0·1 c.cm. of this mixture was at once spread over the surface of fresh agar plates in the manner described before. The proportion of areas developing in each pair of agar plates indicates the destructive action of the sublimate on the phage, or, in other words, the resistance of the particular passage strain to sublimate. From these agar plates some of the areas were again picked off, and thus a second series of passage strains was obtained, which was again mixed with sublimate and treated further, as described for the first series. After nine such passages, the number of phage areas on the agar plate inoculated from the sublimate-treated phage and from the control was approximately equal, thus showing almost complete resistance to sublimate to have developed in the sublimate passage strain. Yet the original phage strain, carried on for an equal number of passages without contact with sublimate, showed complete destruction by the same sublimate concentration. Thus it has been proved that the phage can be completely accustomed to certain concentrations of sublimate, which at the outset had sufficed to destroy it.

Similar experiments were carried out with phenol. The thirty-third passage in phenol was destroyed in two days by phenol 1·9 per cent., the control strain of phage, which had never come in contact with phenol, was destroyed by phenol 1·5 per cent. Analogous results were obtained with a very efficient disinfectant called chloramine (para-toluol-sulfone-chloramide-sodium).

This would appear to be conclusive proof that we can accustom the phage to the deleterious influence of certain disinfectants. Similar results have been published by d'Herelle for the resistance of the phage to acids, but they are not quite conclusive; more exact data in the same direction were since obtained by Asheshov, Schuurmann and for some, but not all, the phage strains examined by Ordelt.

Yet the critic may still raise two objections against the assumption that these results prove the phage to have been really *accustomed* to the disinfectant.

(*a*) It may be affirmed that it is not the phage which varies, but the bacteria; indeed, we know such

variations to occur regularly in bacteria, as in all living organisms. But this contention is not very plausible; for it should be remembered that—e.g., on an agar plate covered with bacteria and showing 100 phage areas, the original implant of the plate would have been only 100 phage corpuscles, but 25,000,000 bacteria. If, as we have seen, differences are found in the behaviour of the individual phage areas, it is surely far-fetched to attribute them to plus- or minus-variation of the bacteria, whose enormous number must tend to equalise such effects. They *must* be attributed to variation in the phage corpuscles.

(*b*) But even assuming this to be true, there arises the further objection that in the filtrate originally employed there might have been present two or more different *species* of phage; perhaps in our endeavour to accustom the phage to an antiseptic we have only weeded out the less resistant kind and retained the highly resistant ones. Bail has indeed shown that in a freshly isolated "raw" phage filtrate there may often be present two or more substrains; they can sometimes be distinguished by the size of the phage areas on agar; by repeated subcultures from one kind of area he succeeded in separating a number of such substrains. In order to invalidate this last objection, I carried out the same experiments with one of these "ultra-pure" substrains, kindly sent me by Prof. Bail, the strain called "Lauda G," which forms characteristic very large areas.

With this pure-line strain virtually the same results were obtained: great variation in the resistance of different passage substrains to chloramine, and after about 30 passages a definite increase of each of them, and therefore also of the average resistance of the passage strains to this antiseptic, as compared with the original strain untreated with chloramine. It is true, after the thirty-eighth passage the resistance of the passage strain again became equal to that of the original strain, but such occurrences are known to occur with bacteria and higher organisms also.

Therefore I believe to have proved the variability of different kinds of the bacteriophage, and the possibility of accustoming them to the noxious effects of certain disinfectants. So far as I can see, these facts allow of no more plausible explanation than that the bacteriophage is a living organism.

WERTHEIM'S HYSTERECTOMY FOR CARCINOMA OF THE CERVIX.

THE RESULTS OF SEVENTY-SIX HYSTERECTOMIES PERFORMED FIVE OR MORE YEARS AGO.

BY W. FLETCHER SHAW, M.D. MANCH.,

PROFESSOR OF CLINICAL OBSTETRICS AND GYNÆCOLOGY, MANCHESTER UNIVERSITY; HON. GYNÆCOLOGICAL SURGEON, MANCHESTER ROYAL INFIRMARY; HON. SURGEON FOR WOMEN, ST. MARY'S HOSPITALS, MANCHESTER.

EVERY new treatment for cancer is hailed with delight and great results claimed for it. Naturally, when these great expectations fail to be realised reaction sets in, but later, if there is any benefit at all obtained from the treatment, the pendulum again swings a little forward and finally, after several years of trial, we are able to assess its true value.

For over 20 years Wertheim's hysterectomy has been performed in this country, and the time has now arrived when we should be able to assess its value and decide whether it has stood the test of time. When it was first introduced it was received with a good deal of silent opposition on the part of many of the older gynæcologists, but some of the younger members took it up enthusiastically though, in a little time, the inherent difficulties of the operation cooled a good deal of the enthusiasm. The difficulties in those days seemed very much greater than they are to-day. Each operation presented some fresh obstacle. What had been found in the last case we were prepared t meet again, and we took precautions against it, bu inevitably something fresh appeared and eac operation became an adventurous voyage in a uncharted ocean. It was at this stage Comyn Berkeley and Victor Bonney did so much to rescu the operation when they published a long series cases with a mortality no more than was justifie by the great benefit conferred. Moreover, by workin together they obtained a large number of cases fo operation and so were able to chart most of th common difficulties which were encountered. Oth gynæcologists who were doing the operation flocke to see their perfected technique, and soon the operatio was being more generally performed on more or le identical lines. The younger gynæcologists who hav commenced to do the operation within the last te years cannot realise the enormous difficulties whic confronted the earlier operators, so many of the difficulties having been removed as the operation ha become standardised.

These earlier recorded benefits due to the operatio have now been supplemented by a further paper b Mr. Victor Bonney,[1] who gives details of all the cas upon whom he has operated more than five years ag 214 altogether. The total mortality is about 15 p cent., but in his later series he has reduced this t 12 per cent. Of the total number operated upo 85, which is just below 40 per cent., were alive an well at the end of five years. These are brilliant results, and must go a long way definitely to establis the operation as the treatment most likely to hold ou a chance of permanent cure. The criticism on th paper is likely to be: "These are the results in th hands of one brilliant operator, and it is not likel they will be equalled if the operation becomes mor generally performed." It is, therefore, the duty every gynæcologist who has a considerable series cases performed more than five years ago to publis his figures with the same honesty as Mr. Victo Bonney, and without any excuse for those who hav died of intercurrent disease or whose future histor has not been followed, and it is most essential tha every operator should keep a complete follow up all his cases. It is for this reason that I now publis the results of the cases upon whom I have performe this operation more than five years ago, 76 altogethe The figures of these 76 cases are as follows:—

Deaths due to operation	16 (21	per cent.)
Recurrences	25 (33	„)
Deaths from other causes	2 (2·6	„)
Untraced	3 (3·8	„)
Alive and well five years after the operation	30 (39·5	„

Operability.

This is one of the least important figures as th percentage must vary very considerably with th type of work which the operator is doing. The youn gynæcologist in charge of a large out-patient depar ment will naturally see more of the very advance inoperable cases than will the more senior man charge of a large number of beds with no out-patie department. Nevertheless, although it is not a important figure and must vary considerably wit different operators, still it does give some indicatio of the type of case he is operating upon, and w divide surgeons roughly into two classes, the one wh operates upon every case where there is a reasonab chance of removing the growth, and the others wh merely choose a very small number of early cases f the operation. In a previous paper[2] I gave m operability rate as 26·8 per cent., but this figure w based on a record of only six months' work. Sin that time I have kept a very careful record of eve case of carcinoma of the cervix which I have see and the number I have operated upon, and I find the last five years my operability rate works out 53 per cent. This figure is less than the rate quot by Victor Bonney, 63 per cent., but is sufficient near to show that I am operating upon the same cla

of case, and give every patient with this disease a chance of the operation if it is at all practicable.

Operation Mortality.

In this series my operation mortality is almost the same as Bonney's for his first 100 cases, though in his later series he has improved this to 12 per cent. At first sight this seems a dreadfully high figure, and it is one which could be easily improved if the cases were carefully chosen, but, in a disease of this nature where, up to now, no other form of treatment holds out anything like such a good chance of cure, it is the duty of the surgeon who does the operation frequently to give each of these otherwise condemned patients a chance, and he should not refuse to operate upon any with a reasonable chance merely because he thinks it will worsen his own statistics. At the present state of our knowledge, apart from this method of treatment, patients with carcinoma of the cervix have very little chance of cure, and if we save only a small percentage of these very advanced cases the mortality is fully justified, as many of them which do recur have a considerable interval of freedom of symptoms and those who die would otherwise have only a short and miserable existence. It should be emphasised that this operation is the most difficult one which the gynæcological surgeon is called upon to perform, and should only be practised by those who are constantly operating and have the opportunity of performing this operation frequently and so perfecting their technique. It is not an operation for a man whose operative work is only part of his daily life, and who is likely only to perform this operation a very few times. The chief cause of death is shock, and the wider the operation is taken the greater the mortality. After shock I find sepsis of the rawed pelvic tissue, and sepsis of the urinary tract, the most common causes of death.

Sepsis of the urinary tract is very difficult to combat. After such a severe operation patients frequently have retention of urine with the necessity of catheterisation, and no matter how carefully this is done there is the liability of bladder infection, as this organ is less resistant after so much damage to its nerve-supply. In a few cases the septic infection tracks up to the kidneys. For some time I have given my patients urotropine, gr. 40, for a few nights before and after operation, but whether this is a real benefit or not it is difficult to determine.

Occasionally we see a case where the growth is obviously very early and the uterus freely movable, but more often the advanced case where the growth has extended on to the bladder wall and the uterus is fixed in the pelvis, and between these is a large number of cases where it is doubtful whether the whole growth can be removed or not. These are cases in which the operation should be given a trial, though necessarily a number will be found so advanced that the abdomen will have to be closed without the operation being completed. In my experience the duration of the symptoms is of little value in determining whether the case will be operable or not. Some with a very short history prove to have a very advanced, inoperable growth. Pain is a most important symptom, and I doubt whether it is ever possible completely to eradicate the growth when once this symptom is established. The cauliflower type of growth which forms a big mass in the vagina is much more favourable than the type which shows very little growth on the cervix but extends upwards in the upper cervical tissues. A growth on to the bladder I consider quite inoperable, and never perform an extensive operation which requires removal of the bladder wall. The thickness of the patient's abdominal wall is another important factor in determining operability. The old teaching was that malignant disease of the cervix occurs in poor, worn-out, thin, anæmic patients, but in my experience some of the fattest patients I have been asked to operate upon have suffered from this disease. A fat abdominal wall, with masses of fat in the bladder wall and pelvis, makes the operation extremely difficult, and I have more frequently abandoned the operation for this reason than because of the extent of the actual growth.

Operation.

The operation, nowadays, is more or less standardised, but I think we should insist upon the term "Wertheim's hysterectomy" being applied only to those cases in which the ureters have been dissected out and the vagina clamped over the growth before removal. There are still certain operators who say they are doing Wertheim's operation, where, in reality, they are only doing a simple panhysterectomy, and it is not fair to compare their results with those who are doing a complete Wertheim's hysterectomy.

Glands.

Many operators lay great stress upon the prevalence of malignant infection of the glands. In my experience the glands are involved very much less frequently than one would expect. Even where the glands are enlarged microscopical investigation shows it is frequently due to septic infection, not to malignant deposits. In his series of 214 cases Bonney found the large number of 43·4 per cent. to have malignant glands, and by carefully compiled tables he shows that this group have a much greater primary mortality and a much higher percentage of recurrence than those without glandular involvement.

Recurrence.

This is the chief test of the operation, and in my experience the majority of recurrences occur in the first or second year. Of all my cases which have suffered from recurrence 81 per cent. have done so in the first two years. If at the end of one year after the operation the patient is perfectly fit and well, putting on weight, and has a good colour, I consider she has a good chance of remaining perfectly free. If, on the other hand, she is rather seedy, with a bad colour, I feel that recurrence will probably take place during the next 12 months, but we must remember that no period of freedom from recurrence warrants us to use the word cure. For some time, five years has been taken as the period which some operators consider as justifying the use of the term, but only last month I heard of two of my patients, one of whom has been perfectly well for nine years, and the other for six years, and now both have recurrence.

Of the cases upon which I performed the operation more than five years ago, there are 76. Of these, 16 died of the operation, 25 have died from or are suffering from recurrence, two have died from other causes (one an operation upon the ureter two years later, and one from tuberculous meningitis four years later), and three cannot be traced. This leaves 30 alive and well at the end of five years, being 39·5 per cent. of those operated upon.

Of cases operated upon more than seven years ago, I have 50 with the following results:—

Immediate death	11
Recurrence	18
Death from tubercle	1
Not traced	4
Alive and well after seven years	16 (32 per cent.)

It would be a simple matter to improve this figure by deducting cases which died from intercurrent disease, cases which cannot be traced, &c., but as the ground for decision whether the operation is justified or not I think the only figures which should be allowed are the total number of cases upon which the operation was completed, and the number of cases which are alive and well after five years. In my case I performed the operation in 76 patients, and of these 30 are alive and well, and so, although I am appalled with the dreadful mortality, I feel compelled to proceed with this operation until some other form of treatment is

definitely proved to be capable of giving a freedom of recurrence over five years to 40 per cent. of the patients to whom such treatment is applied.

Radium.

The chief alternative treatment to operation for carcinoma of the cervix is radium, about which a large literature has sprung up. The application of radium is fairly straightforward, and does not require anything like the technical skill that is necessary for a Wertheim's hysterectomy, and so the difference in results due to this personal factor should be eliminated; in fact the technique employed at the "Radiumhemmet" in Stockholm, from which some of the best results have been published, is one of the simplest. It is therefore very surprising to find such enormous differences in the results published by the various observers. Heyman,[3] from Stockholm, claims 20·29 per cent. of all his cases to be alive after five years and 40·5 per cent. of his operable cases, while Gray Ward [4 5] and Farrar claim 23·6 per cent. of all cases and 52·9 per cent. of the operable cases to be alive after five years.

If these figures can be equalled in other countries then Wertheim's hysterectomy should be abandoned. It is very difficult to criticise figures from other countries but, whilst these observers are absolutely reliable and their figures above suspicion, there may be other factors which we, in other countries, cannot assess. For practical purposes we must remember we are treating cases of carcinoma of the cervix in our own country. We have been using radium extensively for many years, and until our own radiologists can show figures comparable to these we must continue to perform Wertheim's hysterectomy. In Manchester we have had radium used in these cases for 13 years, but so far no extensive figures have been published; and in assessing its value I have to rely upon my own impression of the results on my own cases. Naturally, most of the cases referred to the radiologist are advanced ones, but occasionally an early operable case is sent to them because the patient is suffering from some other condition which precludes operation, but up to the present time I have not found any of these patients free from recurrence at the end of five years.

Some years ago I was very interested in cases which had been made operable by radium, and in 1919 read a paper[6] before the Obstetrical Section of the Royal Society of Medicine along with Dr. A. Burrows, based upon 11 cases. So impressed was I with the effect of radium that, from that time, I made a general rule of having each case of carcinoma of the cervix treated with radium before the operation was performed. I did this after careful consultation and discussion with Dr. Burrows, the radiologist, who felt that radium would act as well before the operation as after, and would give very much less likelihood of fistula and other pelvic troubles.

Of the patients upon whom I operated more than one year ago I find 68 were treated with radium previous to the operation and in 59 radium was not used at all. Of the 68 cases treated with radium, 28 are alive and well to-day—that is 41 per cent.; whereas of the 59 not treated by radium only 18 are alive—that is 32 per cent.

Now that we know more about the action of radium and see how localised it really is, it is difficult to understand how the rays will affect the tissues beyond the line of operation, and lately I have tended to discard the use of radium, but now that I have taken out these figures and find such a considerable difference in the results I feel that probably radium has been of some benefit and it should be given an extended trial to our operation cases.

THE BLOOD PRESSURE IN PSYCHONEUROSIS.

AN INVESTIGATION OF 71 CASES.

BY S. BARTON HALL, M.B., CH.B. LIVERP.,
HONORARY PHYSICIAN, NEW PSYCHOTHERAPEUTIC CLINIC, LIVERPOOL.

SINCE the days when John Hunter said that his life was in the hands of any rascal who chose to annoy him, the influence of the emotions upon the circulatory system has been constantly—though somewhat vaguely—recognised. Whereas knowledge of the mechanical factors concerned in blood pressure has reached quite formidable proportions, the reaction of that mechanism to stimuli of psychical origin has received a comparatively small degree of exact observation. So far as the psychoses and psychoneuroses are concerned, definite findings have been established, the consensus of opinion being as follows. In the psychoses, according to Sir Maurice Craig's investigation,[1] the blood pressure is variable, being higher than the normal in cases of melancholia and the depressed types of manic-depressive insanity, but subnormal in states of mania and agitated melancholia. In the psychoneuroses, neurasthenias, psychasthenias, Craig, in common with other observers, has found the blood pressure to be low. Halls Dally [2] has laid stress upon the rise of pressure occurring in a group of cases in which there is a marked degree of anxiety neurosis, or history of prolonged mental strain. He also refers to the temporary pressor influence exerted by such emotions as fear, anger, or states of worry and great mental activity. The latter aspect of the subject has been investigated in detail by Cannon,[3] to whose work further reference will be made.

Aims and Definitions.

In the present investigation an attempt has been made, first, to compare results with the above findings; second, to examine in greater detail the cases of neurosis in which an abnormally high blood pressure occurs; third, to observe the result of treatment in such cases; and fourth, to investigate the temporary response of the circulatory system to states of increased emotional tone. The cases were not selected, but represent a series to which the same methods of investigation, precautions, and technique were applied. The term neurasthenia has not been taken to include psychasthenia, but rather to denote that state in which the symptomatology is physical rather than mental, associated with a host of subjective symptoms both general, such as the asthenia, and local, in which the symptoms are referred to any or all of the systems of the body. Psychasthenia, on the other hand, has been taken to include that type of case wherein no physical symptoms are evident, but where the complaint is of an asthenic mental state—defective memory, lack of concentrating power, phobias, and obsessions — the reasoning power remaining unimpaired. The two types are, of course, commonly present in the same patient, but in the early stages often appear as distinct entities.

Method, Technique, and Precautions.

To eliminate organic ætiological factors the following measures have been adopted in each case. Thorough physical examination, neurological, cardiovascular, genito-urinary, &c., was undertaken. Investigation as to the patient's life and habits, age with reference to menopause, and as to the possible existence of some septic focus, anæmia, &c. In the majority of cases, too, the patients had been submitted to thorough examination before coming under investigation. Forty-one of the cases were males, and 30 females. With the exception of one patient aged 63, all the ages were between 20 and 60 years.

The technique and method observed were as follows. The instrument used was of the Martin type with a

ıercurial manometer, and the readings were taken y the auditory method and checked digitally. The ulse-rate, the systolic and diastolic pressures were ecorded on each occasion. Each reading was taken fter the patient had rested for at least 10 minutes in comfortable chair, and every possible psychical isturbance had been brought to an irreducible ıinimum. In cases where the pressure was found to e high upon first reading, it was recorded again) minutes later, the emotional response—a term hich will be further explained—being observed and xcluded. The accuracy of the latter reading as a ecord of the patient's blood pressure was confirmed y readings taken a few minutes later. Readings ere taken upon subsequent occasions, always at ıe same time of day.

The precautions taken have been practically ıose advocated by Halls Dally; his formula, too, has een used in working out a scale of normal blood ressures, a latitude of 10 mm. Hg above and below ıis scale of pressures being allowed in order to ve generous interpretation to the expression normal limits." According to these formulæ the andard systolic pressure between the ages of 20 ıd 60 equals 120 + 1/5 of the age. At the age 60 ıe standard systolic pressure is taken as 135, and r each year above this, up to and including age 80, ld 1 mm. Hg. For diastolic pressure 80 mm. Hg taken as standard for 20 years of age, adding mm. Hg for each 5 years up to 60, and 2 mm. Hg r each 5 years between 60 and 80.

lood Pressure in Neurasthenia and Psychasthenia.

To turn to the actual findings, the results of vestigation on the cases of neurasthenia and sychasthenia confirm the findings of other observers the extent illustrated in Diagram I. (Table I.). will be seen here that in the majority of cases 4·9 per cent.) the systolic blood pressure readings are und to be below normal, some of them to a marked egree. It is interesting to note that a number of ıe patients who exhibit pronounced hypotonus are ıose who show the symptoms and signs of circulatory stability. Such a patient will complain that some ight shock, excitement, self-consciousness, or other notional stimulus is followed by "thudding" of s heart or carotid vessels, or by the consciousness of s pulse-beat in limbs, ears, or head. With these is sociated a feeling of warmth and many other bjective sensations. On examination the skin is und to flush readily and to exhibit dermatographia, .e heart sounds are abnormally loud and clear, the pulse is full and bounding, almost of a collapsing quality, though not necessarily increased in rate. Obvious pulsation is observed in the larger arteries such as the abdominal aorta and the carotids. The condition is well demonstrated in several cases of the present series, as, for example :—

A. M., male, aged 30. The condition dated from 1916, when the patient was buried by a shell explosion and suffered from a condition described as "shell-shock," on account of which he was invalided out of the army. He had been able to work for short periods only since that time. When first seen his main complaints were of exhaustion, lassitude, sweating, palpitation, choking sensations, restlessness, and insomnia. The slightest mental excitement or activity, such as might occur from conversation, reading, or being examined, served to exaggerate enormously the cardiovascular activity, and to produce the symptoms

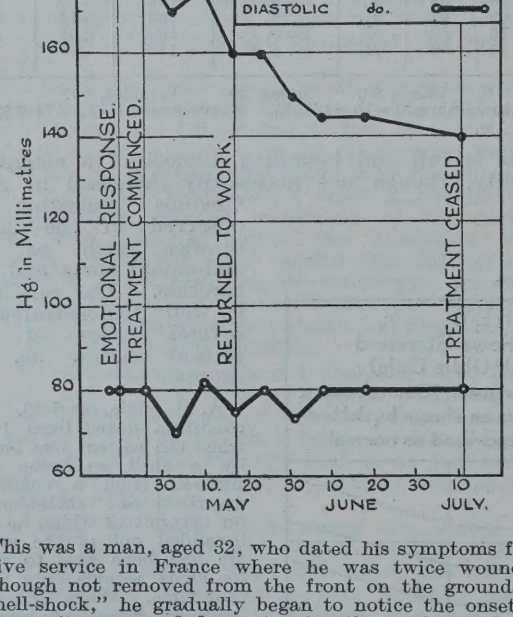
subjective sensations, and signs already described. Physical examination discovered no organic lesion, the response to physical effort was good, the pulse-rate during the occurrence of symptoms was not accelerated, but remained at 70 per minute. The blood pressure in this case was 86/55.

High Blood Pressure in Anxiety Neurosis.

Reference has already been made to a definite group of cases of psychasthenias and anxiety neuroses in which an abnormally high blood pressure occurs. There are 13 such cases in the present series. (See Table II.) This condition is usually associated with anxiety neurosis in some form, and is one in which some worry, fear, or distressing idea continually dominates the patient's thoughts and renders him in a state of continued anxiety and suppressed excitement. The actual cause for anxiety may have no foundation in fact but recurs again and again to the patient's mind because of its painful character. Such an idea gradually absorbs more and more of his attention until a vicious circle is established. The mental preoccupation not only leads to lack of concentrating power and inability for work, but itself causes exhaustion far more quickly than normal mental activity. Mental depression or agitation follows, possibly complicated by insomnia, until at length the patient begins to complain of physical symptoms such as those seen in neurasthenia. On the other hand, the anxiety state may be founded on fact but be out of all proportion to the original cause. A minor business worry may be magnified into impending bankruptcy, or a chance remark into an intended insult.

It is interesting to note too, how, if the condition is treated and the mental state becomes calmer and more normal, the blood pressure falls to within normal limits as in Case 9. Diagram IIA. (Table II.)



This was a man, aged 32, who dated his symptoms from active service in France where he was twice wounded. Although not removed from the front on the grounds of "shell-shock," he gradually began to notice the onset of self-consciousness and depression together with circulatory signs and symptoms as already described. When first seen, eight years after the onset, he complained of dreads of suicide, homicide, and insanity, and also of numerous subjective sensations, tingling sensations in various parts of the body, pressure on the vertex of the head, pains of a wandering character, shooting sensations in the limbs. As seen in the diagram the blood pressure at the commencement of treatment was 180/80. With the relief of the mental condition the figure steadily fell until it came within normal limits. Concurrently with this the physical signs and symptoms cleared up enabling the patient to resume work as a gardener. Six months later his doctor reported that he remained at work and in normal health.

As illustrated, the blood pressure in each case approximated to the normal concurrently with the return to a more peaceful state of mind.

Sir Humphry Rolleston [4] has indicated the importance of ascertaining a possible psychological

TABLE II.—*Effect of Treatment on B.P. in the Anxiety Neuroses.*

N.R. = Not recorded.

The "Before treatment" readings were ascertained by taking the blood pressure several times on different days in order to eliminate emotional variations.

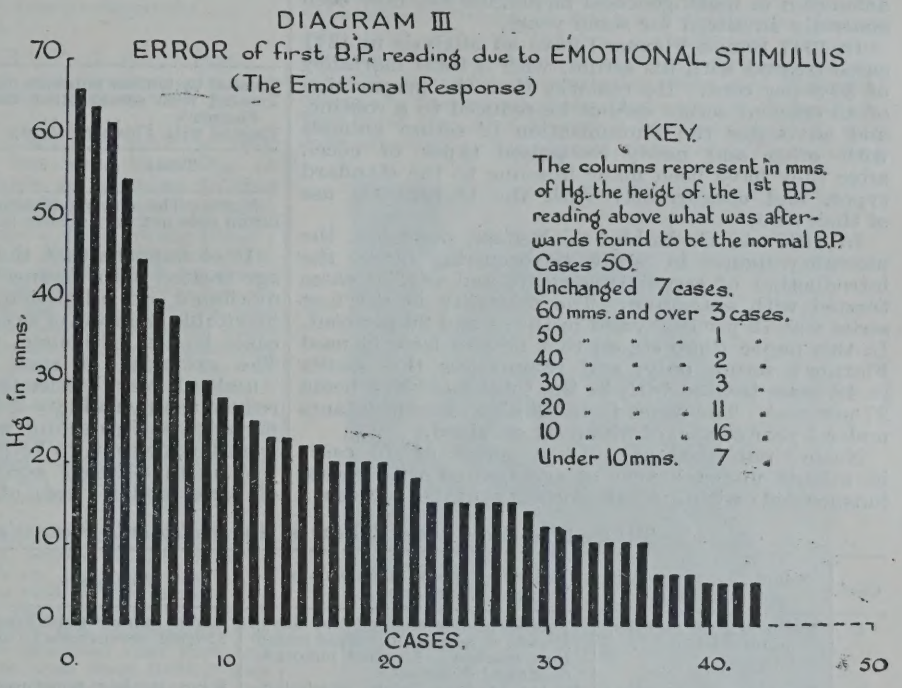
factor in cases of high blood pressure, and the conclusion pointed by the study of these cases—namely the apparent association between the blood pressure and increased emotional tone—may conceivably throw some light upon the ætiology of hypertonus and on those cardiovascular conditions, in the causation of which mental strain has acted as a contributory factor. According to Halls Dally, states of "continued worry and anxiety have a strong action in promoting vasoconstriction over long periods of time, tending ultimately to permanent thickening of the vessel walls." It would appear therefore, that psychical factors are worthy of consideration in the ætiology and treatment of such conditions. From the therapeutic point of view an attempt has been made to show the value of combating the mental condition in the type of case described above. Ziegler and Levine [5] have recorded an increase in the basal metabolic rate resulting from emocional stimuli, an increase which was accentuated in psychoneurotics. They also noted the changes in the colour of the skin, the fine tremors, differences in the rate and amplitude of respiration, &c. They used these observations to show that lying still in bed was no very accurate criterion even of physical rest. So in the treatment of hypertonus where mental factors have apparently played a part in the causation —lack of attention to the psychological condition would be a serious omission.

Response of Blood Pressure to Momentary Emotional Stimuli.

A third feature of interest which has appeared during these investigations is the momentary variation of blood pressure—often to abnormal limits—which is seen following some sudden emotional stimulus. It is a commonplace of blood pressure observation that the first record may be unreliable, and an attempt has been made to find out just how far this is so. Of the 50 cases examined to this end, 43 showed a rise of pressure beyond the real blood pressure as ascertained a few minutes later. Of these 43 cases 35 showed a rise of 10 mm. Hg or over, and 13 a rise of pressure beyond normal limits. (See Diagram III. As has already been explained in the details of precautions taken these patients were under no particular emotional stress other than the strangeness of surroundings and apparatus, yet the first record were erroneous to the extent illustrated. In several of the cases a second, and even a third, reading failed to elicit the actual blood pressure, so that had no

reat care been taken the observer would have been ridely misled as to the exact state of tonus.

Without going into more wearisome analysis of the gures in all the cases, the unreliability of blood ressure readings in neurotic or merely highly strung emperamental patients is clearly demonstrated. single record of blood pressure taken during the hysical examination of such a patient is scarcely kely to prove accurate, for, though to all intents and urposes he may be at rest, his state of mental xcitement, however slight n degree, may cause ufficient circulatory hange to produce inaccuracy. The results also how the cardiovascular ystem as a sensitive indiator responding to mental rocesses which result om environmental timuli, of mild degree, ccurring in the absence f physical activity. The ractical point arising om these temporary bnormalities of blood ressure is in cases where reat stress is laid upon he record of blood ressure. In recent years, ossibly to a greater xtent in America than n this country, the estiation of blood pressure as played an increasing art in medical examinaon, especially that for fe assurance, and it is onceivable that by temorarily raising the blood ressure the emotional actor might contribute o a pessimistic estimate f the patient's condition nless elaborate precautions were taken. Again, consideration of the emotional variations in lood pressure may assist the physician to regard arily records of treatment by preparations which re credited with lowering the blood pressures ome 10 or 20 mm. Hg. This emotional response ould appear to illustrate the way in which igh pressures of the more persistent type, like hose already described, occur, and which fall, nly with relief of the emotional stress. Turning o explanation of these phenomena—the sudden motional variation and the high pressure of longer uration seen in anxiety neuroses—much help may e derived from the work of Cannon. Cannon has hown that an increase of adrenalin in the circulating lood follows increase of emotional tone, as in fear, nger, &c. He ascribes the activity of the suprarenals o the general sympathetic stimulation which occurs nd which shows itself in numerous other ways such s dilation of the pupils, vaso-constriction, activity f the sweat glands, &c. The effect of adrenalin tself, however, is to stimulate sympathetic action, o that possibly thereby a double influence is brought o bear—direct and immediate sympathetic activity esulting from increased emotional tone, and indirectly roduced sympathetic activity resulting from discharge f adrenalin into the circulation. Some combination f these factors, then, may account for the temporary ise in blood pressure which follows emotional timulation. With regard to the more persistent form f high pressure found in the anxiety neurosis, it is ossible that, as has been already hinted, the vicious ircling of the patient's mental processes causes a ontinuous emotional stress, the factors just described xerting a more chronic effect upon the circulatory ystem—the " continued vaso-constriction " of Halls Dally. Such an explanation, too, might throw some ight on the question of high blood pressure in cases where, without the occurrence of any neurosis or cardiovascular disease, a life of continued mental stress and anxiety appears the sole ætiological factor.



Summary and Conclusions.

To summarise the conclusions pointed by this investigation. (*a*) As was found by previous observers, the blood pressure in neurasthenia and psychasthenia is abnormally low. (*b*) In cases of prolonged mental strain or anxiety neurosis, and in a small group of psychasthenics, the blood pressure may be abnormally and persistently high. (*c*) The blood pressure where abnormally high falls to within normal limits as the mental condition yields to treatment. (*d*) The initial blood pressure readings in highly strung or neurotic patients may appear to be higher than is actually the case even to the point of considerable abnormality. The sudden rise of pressure is excited by some extraneous stimulus to the emotions, thence directly through the sympathetic system, or indirectly by sympathetic system and adrenal glands, to the vaso-motor system. It is possible that continued emotional stress causing frequent or continuous vaso-constriction may lead ultimately to permanent thickening of the vessel walls. (*e*) The patient's mental state plays an important part in the ætiology and treatment of hypertonus, which occurs in functional cases.

It is worthy of consideration in those more chronic cases of high blood pressure and in cardiovascular conditions which appear to result from mental strain.

QUEEN'S HOSPITAL, BIRMINGHAM.—The extension to the Queen's Hospital, consisting of a building containing 120 beds with three operating theatres, will be opened on Nov. 16th.

CRISIS AT SWANSEA HOSPITAL.—Swansea Hospital is in a serious financial position, having very nearly reached the limit of its overdraft of £60,000 at the bank. Unless means are found of increasing its revenue there will be no alternative but to close portions of the hospital and bring monthly expenditure into line with monthly revenue.

MENINGOCOCCAL MENINGITIS IN INFANTS AND CHILDREN.

TREATED BY FLEXNER'S SERUM.

BY G. KENNEDY THORNTON, M.B. CAMB.,
LATE RESIDENT MEDICAL OFFICER, QUEEN'S HOSPITAL FOR CHILDREN.

THE value of intrathecal infections of an efficient antiserum in meningococcal meningitis has now been generally admitted for some years.

In 1917 Simon Flexner [1] gave an analysis in 1211 cases treated with his serum, with a total mortality of 30·8 per cent. He remarks that the preparation of an efficient serum cannot be reduced to a routine, and advocates the immunisation of serum animals with other and newly recognised types of cocci, after they have been made immune to the standard types, and concurrently with the therapeutic use of their sera.

In 1917 A. G. Robb,[2] of Belfast, published the mortality figures in 300 cases occurring before the introduction of serum treatment, and of 270 cases treated with antiserum. The mortality in the first series was 72 per cent., and in the second 26 per cent. In this paper Robb stated that he had latterly used Flexner's serum only, and summarises the results in 48 cases treated with it, the total mortality being 27 per cent. The series includes nine cases in infants under 1 year of age, of whom six survived.

Neale [3] published in 1918 a series of 76 cases in infants under 1 year of age treated with serum (unspecified) with a total mortality of 50 per cent., and quotes Flexner's estimation of the pre-serum mortality, under this age, at over 90 per cent.

During the war good results were obtained by the use of polyvalent sera prepared in this country. Helen Mackay [4] published in 1920 a series of eight consecutive cases, all in children under 8 years of age, treated between September, 1916, and July, 1917, with serum from the Lister Institute. All of these survived.

Reference to the records of the Queen's Hospital for Children from 1917 to the present time, where sera produced in this country were in general use till July, 1925, shows that the results were, on the whole, disappointing. The number treated since that date with Flexner's serum is small, but the results of treatment, as far as the immediate life-saving is concerned, have been such as to suggest that Flexner's serum is worthy of a more extensive trial in this country, especially in the case of young infants.

TABLE I.

A = Analysis of 32 cases occurring in children under 14 years of age, 1917–27.
B = Twenty-one cases included in Series A, under 1 year of age.

—	A			B		
	Total.	Recovered.	Died.	Total.	Recovered.	Died.
Treated by lumbar puncture only	5	1	4	5	1	4
Treated with serum other than Flexner's	17	5	12	11	1	10
Treated with Flexner's serum	10	7	3	5	4	1
Total	32	14	18	21	6	15

NOTE.—The average duration of disease before treatment was begun does not vary greatly in the three groups.

It so happens that the five cases under 1 year of age treated with Flexner's serum do not include any moribund on admission. In a larger series the inevitable inclusion of a certain percentage of moribund cases would, of course, increase the mortality-rate. The exclusion of such moribund cases from the "under 1 year" series treated with other sera would reduce the mortality—if it be permissible to speak of percentages in dealing with such a small number—from 90 per cent. to 75 per cent.

A more detailed account is given in Table II of cases under 1 year of age, treated with Flexner's

TABLE II.—*Cases under 1 Year of Age treated with Flexner's Serum.*

Case.	Names, age, and date of admission.	Type of onset, and state on admission.	Treatment.	Result.
1	Doris K., 3 months, admitted 26/1/26.	Feverish and fretful for four days. Had fit on admission. Head retraction marked. Lumbar puncture confirmed diagnosis.	Seven lumbar punctures; 35 c.cm. serum used in all.	Temp. level 17 days from admission. Appeared normal on discharge, 24/2/26.
2	Irene G., 4 months; admitted 31/1/26.	Ill for 14 days before admission. Had two fits. Marked head retraction. Lumbar puncture confirmed diagnosis.	Four lumbar punctures; 50 c.cm. serum used in all.	Temp. level 16 days from admission. Appeared normal on discharge, 25/2/26.
3	Edward O., 10 months, admitted 29/9/26.	Onset of illness four days before admission, with vomiting. Fontanelle bulging. Lumbar puncture gave turbid fluid containing polymorphs but no organism.	Five lumbar punctures; 50 c.cm. serum used in all.	Temp. normal 10 days from admission and meningeal signs disappeared. Convalescence complicated by multiple joint effusions. Good recovery on discharge 29/1/27.
4	Doris M., 3 months, admitted 31/12/26.	Sudden onset with vomiting day of admission. Fontanelle bulging. Lumbar puncture gave turbid fluid containing polymorphs and Gram-positive cocci.	Four lumbar punctures; 25 c.cm. serum used in all.	Died 16 days after admission. Meningococci found in later lumbar puncture as well as Gram-positive cocci.
5	Harry T., 4 months, admitted 20/2/27.	Admitted with right basal pneumonia. Chest was clear and temperature normal on sixth day. Temperature rose again, 10/3/27, and head retraction developed. Lumbar puncture, 16/3/27, gave turbid fluid containing meningococci.	Eight lumbar punctures; 90 c.cm. serum used in all.	Temp. level three days from first administration of serum. Head retraction persisted till 24/3/27. Is now making good recovery.

In Case 3 no meningococci were found on lumbar puncture, but in view of the almost inevitably fatal results of other meningeal infections leading to polymorphonuclear reactions in the cerebro-spinal fluid, this case has been retained in the series. As against this, in Case 4, the meningococcal infection eventually proved, was complicated from the first by infection with a Gram-positive coccus as well.

The Flexner serum used at the Queen's Hospital was obtained in part from the New York City Research Laboratories, E.16th Street, New York, from which address it may be had at any time on payment. Much of that used was supplied gratis by the New York State Department of Health, Albany, N.Y., on condition of a report on cases being sent. Thanks are due to this department and also to Dr. Robb of the Purdysburn Fever Hospital, Belfast, who ha

n several occasions sent supplies of serum in mergency, when stocks were short. I am indebted o the physicians of the Queen's Hospital for per-ission to publish details of cases.

A CASE OF CEPHALIC TETANUS.

BY WILLIAM FLETCHER, M.D. CAMB., M.R.C.P. LOND.,
DIRECTOR, INSTITUTE FOR MEDICAL RESEARCH;
AND
J. P. FITZPATRICK, L.R.C.P., L.R.C.S. IREL.,
MEDICAL OFFICER IN CHARGE OF THE DISTRICT HOSPITAL, KUALA LUMPUR, FEDERATED MALAY STATES.

TETANUS limited to the head and neck is very ncommon, and, unless one has some knowledge of ıe signs and symptoms which are peculiar to this ɔrm of the disease, the diagnosis is not always easy.

The subject of this report was a strong young Chinese ɔrter who had been employed in lifting bales and boxes ɔ a warehouse in Kuala Lumpur. He attributed his illness ɔ an accident which had befallen him 20 days before we ıw him in consultation. A box had fallen on to his head ıd had made a small punctured wound above the outer ıd of his right eyebrow, whence his friends had extracted vo long splinters of wood which had been driven beneath ıe skin of the temple. Ten days after the accident he ınd that he was unable to close his right eye or to open ıs mouth to its full extent. A few days later he began to cperience difficulty in swallowing, and was brought to the ɔspital by his friends with the following note: "Siew Check ıys he has flames in his throat and begs you to give him ɔme medicine to overcome this trouble. Owing to this he ıable to speak."

When we saw him on August 28th the wound on his rehead was completely healed, leaving a scar which is ıown in the photograph taken on the same day. The ce was paralysed on the same side as the wound; the ght eye could not be closed, the corner of the mouth ng down, and the naso-labial fold was obliterated. The ws were stiff and could not be separated more than half ı inch. If the patient tried to open them further they osed with a snap. Sometimes, in desperation, he put s fingers in his mouth and tried to pull it open by force. he contraction appeared to be more marked on the right de than on the left. He was excited, restless, and full terror, like a man with rabies. From time to time there as a tic-like twitching of the muscles on the left side the face, but there was no stiffness of the neck, and the ead could be turned freely. The chest and abdomen oved normally in respiration. The use of the limbs was ıimpaired; the patient could use his fingers to pick up ıall objects, and he walked quite easily. He was able to ticulate, but made us understand, by striking his throat, at it pained him to talk. He could neither cough, hawk, ɔr spit. On account of his distress the senses of taste, ıell, and hearing were not investigated. His temperature as 102° F. in the axilla and the pulse-rate was 110 to the inute.

Such was his condition when in comparative repose, but ıen he attempted to swallow the result was terrible. hile we were examining him he asked for some iced water, ıt no sooner did he put the cup to his lips than he was zed with violent spasms of the throat, jaws, and left side the face. The small amount of fluid which had entered s mouth was shot out again with a hissing sound; short arp hisses—like the exclamatory "hist" which is used attract attention—followed each other at intervals of out half a second. With each hiss the head was jerked ward by a spasm of the sternomastoids, and sometimes e hiss ended in a sharp sound like a bark. The patient ust have remained in this torture for a minute or more, ıt the spasms did not spread below the neck. He was ting on a long chair when the attack began, and during he got up and sat down on the other side.

During the night he was very restless, continually getting t of bed and walking about. From time to time the asms came on, and then he was beside himself, struggling d hitting out at anyone who went near him. He drove ay his friends, saying that he did not wish to see them. On the following morning he was very restless and much aker. The skin temperature was subnormal; the pulse-te had increased to 120. He had no peace without morphia. ıe twitching spasms on the left side of the face occurred ery second. Occasionally a spasm spread to the platysma the neck. Sometimes there was twitching of the muscles the arms. He refused to put anything in his mouth, and an attempt to feed him through a tube produced the most violent spasms. Sometimes he would bathe his parched lips with water, hanging his head over the side of the bed to prevent any drop of the fluid passing into his mouth. He became rapidly exhausted, and on the next day his pulse was imperceptible. There had been no ophthalmoplegia hitherto, but now there was external strabismus of the right eye, which was corrected whenever he focused his gaze upon a definite object. He died at noon on August 30th, about three weeks after the injury and 12 days after the appearance of the first symptoms.

Courtois-Suffit and Giroux, in their war manual on abnormal forms of tetanus,[1] divide the disease into four clinical types: (1) without paralysis, (2) with facial paralysis, (3) with oculo-motor paralysis, (4) with hypoglossal paralysis. The case described belongs to the second group, that with facial paralysis. This form was first described by Rose in 1872, who drew attention to the characteristic triad of prominent

Photograph of patient with cephalic tetanus.

signs which accompany it: (*a*) A wound in the area supplied by the cranial nerves. (*b*) Facial paralysis, generally on the same side as the wound. (*c*) Tetanic spasms of the masseters, the facial muscles, the back of the neck, the pharynx, and the œsophagus. Poan de Sapincourt named it facial tetanus, and drew particular attention to its insidious onset, its slow development, and its treacherous progress.

The point of inoculation in this form of tetanus is always a wound of the head, usually situated in the region innervated by the facial nerve and more often in the zone supplied by its superior branch. The incubation period is generally about eight days, but it may be as short as two or as long as 24. The disease begins, as a rule, with stiffness of the jaws, which is shortly followed by difficulty in speaking and in mastication. The trismus at first is unilateral and on the same side as the wound. One-sided spasmodic contractions of the facial muscles commence soon after the trismus; they usually affect the paralysed side of the face, but sometimes they may be limited to the opposite side, as they were in our patient. In the latter case one-half of the face may wear an expression of profound apathy while the spasms twist the other into a grimace of terrible fury. When the spasms spread to the pharynx and œsophagus, as in the case described, the prognosis is very grave; each attempt to swallow brings them on; sometimes the sight or even the mention of a drink will start an attack, and the condition amounts to

[1] Les formes anormales du Tétanos., M. Courtois-Suffit and R. Giroux, Paris, 1926.

a veritable hydrophobia. The muscles at the back of the neck are usually affected, and cervical opisthotonos frequently occurs during a seizure. As the disease progresses the spasms tend to spread to the rest of the body, but this did not happen in our patient's case, though it might have done so if he had lived longer.

Facial paralysis is an early symptom, but it usually appears later than the trismus. It is limited to the same side as the wound, but it may be bilateral if the injury is in the middle line. In some cases where the wound is close to the eye there may be ophthalmoplegia on the same side; occasionally this appears before there is any trismus, and diplopia may be the first sign of the disease.

The absence of fever is a peculiarity of this form of tetanus, but the temperature rises as the spasms spread. The pulse is always rapid. The prognosis is grave; 16 out of 22 cases cited by Courtois-Suffit and Giroux died before the tenth day, and one died after the disease had lasted more than two weeks.

A CASE OF
PROLONGED TACHYCARDIA, ASSOCIATED WITH CONGENITAL HEART DISEASE,
IN A CHILD FIFTEEN MONTHS OLD.

BY H. B. RUSSELL, M.D., M.R.C.P. LOND.,
HYSICIAN TO OUT-PATIENTS, QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY; CHIEF ASSISTANT ELECTROCARDIOGRAPHIC DEPARTMENT, ST. THOMAS'S HOSPITAL;
AND
J. B. ELLISON, B. CHIR. CAMB., M.R.C.S. ENG.,
HOUSE PHYSICIAN, QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY.

THE unusual features in this case are due to the fact that a ventricular rate of about 300 beats per minute was maintained without intermission for several days on end, without signs of severe cardiac failure or distress. The following is an account of the case up to the present date.

History of the Case.

Edna R., the first child of young and healthy parents, was born in August, 1925. The confinement was easy, and nothing was noticed wrong with the baby. There is no family history of heart disease. The child was breast fed, and appeared perfectly normal for the first four months, but then commenced to have attacks which the mother referred to as "fits." These consisted of a slight and sudden rigidity of the child, lasting a few seconds only, and followed by a very brief period of doubtful loss of consciousness. No cyanosis was noted during the attacks, but definite blueness of the lips was observed if the child cried. The attacks were intermittent, intervals of several days frequently occurring, to be followed by perhaps a dozen "fits" in 24 hours. There were no after-effects.

This state of affairs continued until the afternoon of Nov. 13th, when the child had an attack. It was immediately apparent that this was more severe than any of the previous ones. Loss of consciousness was obvious and definite cyanosis occurred. The child was immediately taken to the nearest doctor, but had completely recovered by the time his house was reached. She was taken home and appeared perfectly well again for two hours, when another and yet severer attack occurred. On this occasion the child was brought up to hospital, and when first seen in the casualty department was thought to be dead. The child was of a greyish-blue colour, completely flaccid, respirations had ceased, and at first nothing could be heard on listening over the cardiac area, although a faint fluttering sensation was perceived when the hand was laid over the epigastrium. In the course of the next few seconds definite heart sounds were heard, for the first few minutes at irregular and frequently long intervals. The child yawned and respiration recommenced. About one minute later the heart beat became suddenly regular, taking on a rate of approximately 300 beats per minute. Consciousness had been completely regained.

Condition after Admission to Hospital.

After admission to the ward the child was still markedly cyanosed and rather restless, but in no great distress and making no attempt to sit up. The heart continued to beat very rapidly with a perfectly regular rhythm. On palpation the apex-beat was forcible and of maximu intensity in the fourth left intercostal space, a quarter of inch outside the nipple line. The cardiac dullness extend from the second rib above, the apex-beat on the left, and quarter of an inch beyond the right border of the sternu On auscultation the first cardiac sound alone was audib loud and explosive in character, and perfectly regula no murmurs were heard. Every beat was transmitt palpably to the wrist, but owing to the rapidity the pul was uncountable. An attempt was made by auscultati

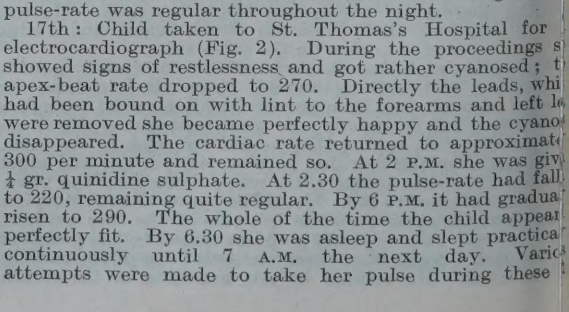
fingers or toes. No change whatsoever in the cardi condition. A polygraphic tracing from the apex-beat ga the rate as 300 per minute. Attempts to get veno and arterial tracings failed. The child took plenty milk throughout the day and slept quite a lot. Duri the night she was less restless and slept well. Repeat

FIG. 3.



Electrocardiogram (lead II.) taken when the heart was beat at 114 per minute. Time marker = 1/5 sec.

pulse observations proved that it remained persisten rapid.

15th: Cyanosis almost gone. Restlessness qu disappeared. No change in the cardiac condition: ape beat rate 300 per minute. Child taking milk well but refus anything else. Passed a good night. Pulse-rate stead maintained. A polygraph tracing was obtained from t carotid (Fig. 1.)

16th: No cyanosis. No restlessness. Child appeared be perfectly well and happy. Apex-beat rate 300 exact Cardiac condition precisely as above; the apex-beat s in the fourth space, a quarter of an inch outside the nip line. No further increase in the dullness to the right. T pulse-rate was regular throughout the night.

17th: Child taken to St. Thomas's Hospital for electrocardiograph (Fig. 2). During the proceedings s showed signs of restlessness and got rather cyanosed; t apex-beat rate dropped to 270. Directly the leads, whi had been bound on with lint to the forearms and left le were removed she became perfectly happy and the cyano disappeared. The cardiac rate returned to approximat 300 per minute and remained so. At 2 P.M. she was giv ¼ gr. quinidine sulphate. At 2.30 the pulse-rate had fall to 220, remaining quite regular. By 6 P.M. it had gradua risen to 290. The whole of the time the child appear perfectly fit. By 6.30 she was asleep and slept practica continuously until 7 A.M. the next day. Varic attempts were made to take her pulse during these

urs, but unfortunately no results were obtained that be relied on.

8th: Child seemed in perfect condition. Pulse-rate only and quite regular. During the course of the day s fell to approximately 100 per minute, at which rate it ained until her discharge from hospital 14 days later. Examination of the heart now revealed very altered ysical signs. The apex-beat was in the fourth left ercostal space, a quarter of an inch internal to the nipple (i.e., half an inch nearer the sternum). The right limit cardiac dullness was at the right sternal edge. On cultation the heart sounds were normal and a loud tolic murmur could be heard all over the cardiac area, ring its point of maximum intensity near to the left sternal e over the fourth intercostal cartilage. There was no ill.

The history of the rest of the stay in hospital is quite eventful. A second electrocardiograph was taken at Thomas's Hospital (Fig. 3) on Nov. 24th.

The following special examinations were performed: X ray of chest: cardiac shadow to the right a little er than normal. 2. Blood count: entirely normal. Wassermann reaction (blood), negative. Apart from the liac condition the child appeared to be perfectly normal every way. After her discharge the child was seen on eral occasions in the out-patient department and appeared be quite fit. Pulse-rate circa 100 per minute.

On Jan. 12th, 1927, the child was brought to hospital, the ther complaining of no symptoms. On examination her rt was found to be beating at the rate of 240 a minute. appeared to be perfectly fit and was in no way distressed. re was no cyanosis. She was readmitted and put on nidine sulphate 1 gr. twice a day. The tachycardia, aining fairly constantly at 240 beats per minute, tinued for three days and then commenced to slow, ing 48 hours to fall to about 100. The quinidine was tinued for five days, 10 gr. being given in all. She kept in hospital one week after her pulse had fallen to mal and was discharged perfectly fit. On this occasion re were no symptoms whatsoever.

The chief interest of the foregoing case lies in the t that the ventricles were able to respond, over a ly prolonged period, to an exceedingly rapid raventricular stimulus. A somewhat similar dition was reported by Dr. J. L. O'Flyn [1] in 1925; this case, however, no congenital heart lesion was sent. The prognosis in the present case is likely be poor. It seems probable that further attacks l occur; in addition congenital heart disease is initely present. The treatment of such a case is satisfactory. The question as to whether the ninistration of quinidine had any effect on the se-rate is very problematical.

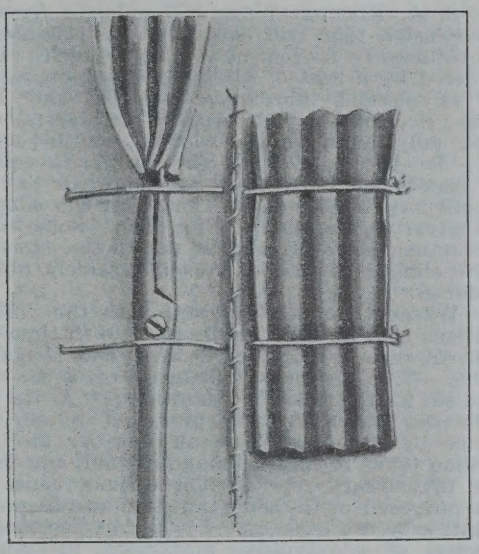
NOTE ON A METHOD OF SUTURING THE FAT ABDOMINAL WALL.

By ARTHUR EDMUNDS, C.B., M.S. LOND., F.R.C.S. ENG.,
SURGEON TO KING'S COLLEGE HOSPITAL.

In suturing an abdominal wall with a thick layer of fat, it is necessary to approximate the deeper ers of the fat, to avoid dead spaces. The large ches which are inserted, however, cut into the n, making ugly scars, and until they are removed patient is usually uncomfortable. There are ny devices in use to overcome this difficulty, such ying the sutures over gauze or a frame, or threading m through short lengths of drainage tubing. I nk the following method worthy of trial, as it is ple and effective.

The suture to employ is the eversion stitch described me [2] several years ago; this is inserted well away n the wound on one side, picks up the whole kness of the fat—or even the deeper tissues if sion stitches are required—and emerges at a responding point on the other side. It is then sed back in the reverse direction, picking up the reme edges of the incision on the way, and is loosely l. This leaves a loop of suture on either side of the wound lying flat on the skin. To prevent these loops cutting into the skin I use the corrugated rubber sheeting which Messrs. Allen and Hanbury prepared for me during the war.[3] Most instrument makers sell it now. Two pieces of this are cut, as wide as the loops and as long as the wound, the corrugations lying parallel to the wound. When enough sutures have been introduced, usually about an inch apart, a pair of long artery forceps is passed under the loops of the sutures on one side; the rubber sheeting is then

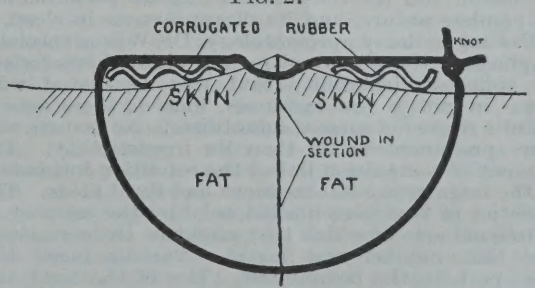
FIG. 1.



The corrugated rubber is shown in position on the right of the figure. On the left the rubber is grasped by the forceps ready to be drawn under the sutures. Two sutures only are shown for simplicity.

compressed laterally, grasped by the forceps, and drawn under the row of suture loops. (This will be readily understood by referring to Fig. 1.) This is then done on the other side of the wound, which may gape a little between the sutures. It is usually possible to adjust the edges with a pair of dissecting forceps so that they are accurately apposed; or, if the surgeon

FIG. 2.



Schematic section of wound, suture, and rubber.

prefers it, a row of running sutures may be inserted. These need not be tied and can be removed as soon as the wound has agglutinated—that is to say, in three or four days. The final arrangement is shown in diagrammatic section in Fig. 2.

If drainage is required there is plenty of room between the big stitches, and the presence of the rubber will not be found to complicate matters at all. When the stitches are to come out, they should be cut over the rubber on the side opposite to the knot, so that they will draw out simultaneously from the deep and superficial punctures.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Continued from p. 505.*)

SECTION OF NEUROLOGY.

WEDNESDAY, JULY 20TH.

THE first session of this Section was held under the presidency of Prof. EDWIN BRAMWELL (Edinburgh), and was devoted to a discussion on the

TICS AND ALLIED CONDITIONS.

Dr. S. A. KINNIER WILSON (London) referred to the confusion that still existed in the classification of involuntary movements; the student being bewildered by a host of ill-differentiated expressions such as electric, fibrillary, variable, and habit choreas, electrolepsy, habit spasm, myospasm, myoclonus, polyclonus, paramyoclonus, and myoclonotonus. The first duty of the clinician was to separate such classes of movement as appeared to have distinctive characters and to insist on the adoption of an unvarying terminology for each. Some of the above terms, however, bad as they were, stood for definite clinical entities and would scarcely now be abandoned.

Dr. Wilson then dealt in turn with the different definitions of a tic that had from time to time been advanced, such as those of Cruchet and Meige and Feindel. The distinctive features of a tic were embodied in the latter's definition: "A tic is a coördinated purposive act, provoked in the first instance by some external cause or by an idea; repetition tends to its becoming habitual, and finally to its involuntary reproduction without cause and for no purpose; at the same time its form, frequency, and intensity are exaggerated; it thus assumes the characters of a convulsive movement, inopportune and excessive; its execution is often preceded by an irresistible impulse, its suppression associated with malaise. The effect of distraction or volitional effort is to diminish its activity; in sleep it disappears. It occurs in predisposed individuals, who usually show other indications of mental instability." The important points were the psychical origin of tics, the existence of a psychical defect in impairment of volition, and of a motor defect in the disfigurement or caricature of a normal movement, repeated in season and out of season, but usually containing the recognisable germ of what was once a purposive act of cortical origin; the malaise that accompanied its repression and the relief succeeding its performance, its painless nature, and its disappearance in sleep.

Passing to the symptomatology, Dr. Wilson specially emphasised the abnormal mental state characterised by volitional instability that was associated with tics; in not a few instances, indeed, there was a definite degree of mental infantilism. No feature was more prominent in tic than its irresistibility. The element of compulsion linked the condition intimately to the large group of obsessions and fixed ideas. The varieties of tics were limited only by the number of functional acts of which they might be the caricature, and that number was legion; various facial tics were perhaps the commonest. Tics of the head and neck were also common—nodding, rolling, shaking, &c. Protean tics of the arms occurred—e.g., scratching, rubbing, stroking, pounding. Tics of the trunk and lower limbs were less common. Behind all tic phenomena lay a psychical predisposition. The common association of tics with mental defect and imbecility effectually precluded any other view. In some cases, possibly the majority, the tic made its appearance as the expression or outward manifestation of an unconscious desire, or of a desire that was often but half hidden from consciousness. Dr. Wilson's experience confirmed that of Meige and Cruchet, that tics rarely accompanied hysteria, yet in its egocentricity and failure to govern emotions the temperament of the tiqueur undoubtedly recalled that of the hysteric. Any purposive coördinated act passed by dint of repetition into a habit, an acquir automatism, nor did its character of necessity chan if its raison d'être disappeared. Should the now pu poseless habit assume an exaggerated form and haphazard incidence it had degenerated into a t Movements of defence against a source of irritati sufficed in some instances to set in motion t processes leading to a tic. Finally, there was t possibility of a tic being engendered on the basis pre-existing involuntary movements of another cla of which the passing of choreic into tic reactions w probably the best known example.

Prognosis depended upon the degree of volition impairment of the patient; in some children ti were purely transient; in some adults persiste treatment might certainly effect a cure. The old the patient and his tics, the less favourable were t chances of relief. Treatment resolved itself und the following headings: (1) General hygienic measu —an aim in life, suitable environment, especially t removal of a spoilt child from over-fond paren disciplinary régime to develop self-control, eliminati of septic foci, and care of general health. (2) Sedati medicinal treatment might benefit every now a then, especially when the pathological habit was engrained in the nervous system as to have sh altogether its psychical element. Many cases in ou patient practice were benefited by a course of bromi in comparatively small doses. (3) Hypnotic a other forms of suggestion had benefited some record cases, but Dr. Wilson's own experience had not be reassuring: the same observation applied to psych logical technique generally. (4) The principle treating tics by muscular drill or re-education h justified the confidence placed in it. Brissau scheme consisted in requiring the patient to perfectly still for increasing periods of time, from second or two at first to minutes and even hou The reverse of this method was to cause the patie to innervate the tic groups but in ways contrary those executed involuntarily. It was a good plan see this programme carried out in front of a mirr

Prof. G. C. GUILLAIN (Paris) confined his observ tions to spasmodic torticollis, which in his experien frequently had an organic basis. He had seen su torticollis in association with pyramidal syndrom and organic familial spasmodic paraplegia, as well in various post-encephalitic states.

Dr. A. F. HURST (London) dealt with vario visceral tics. Most cases of so-called flatulence we in reality due to "aerophagy," or air-swallowin An attempt at belching for the relief of alleged flat lence resulted in the swallowing of air; repetition the act caused more air to be swallowed, until such a accumulation occurred that it was eventually expelle Explanation of this mechanism to the patient oft resulted in cure. Other visceral tics were those sniffing and some forms of coughing, the latter oft in association with asthma.

Prof. R. CRUCHET (Bordeaux) summarised t medical literature of tics from the time of Charl Bell (1830), and Marshall Hall (1852). Tics we characterised by repetition in an involuntary, inte mittent, and absurd manner, at irregular interva with an exaggerated frequency. Their executi was imperious and irresistible; their performan could be delayed, but eventually they got the bett of the will. He entirely agreed that associated wi tics was an abnormal mental state characterised mental infantilism, instability of ideas, inconsistenc carelessness, impulsivity, and loss of judgment. regards treatment, Prof. Cruchet favoured the meth of "respiratory gymnastics" which was especial beneficial in children.

Dr. B. SACHS (New York) was pleased to he Dr. Wilson emphasise the frequent psychogen origin of tics and the association of mental instabilit Nevertheless, it was relatively rare to find any mark concomitant mental disturbance. So many tics we begun early in life that it was essential to atta them at that period. Many tics might have be checked at their beginning if the physician had been

vere disciplinarian. Kindly but firmly the young queur must be told that the tic must stop and that e is the one to stop it.

Dr. STANLEY BARNES (Birmingham) believed that ily people of a nervous temperament, mainly herited, were liable to tics. They occurred, in his perience, more commonly in childhood and adolesnce than in adult life. He agreed with Dr. Sachs to treatment; he himself followed the same urse, relying chiefly on discipline.

Dr. GRAINGER STEWART (London) said that tics ight arise from seeking a pleasant sensation or in oiding an unpleasant one. He agreed that the ajority were psychogenic in origin, and cited a case which the tic had disappeared following revival der hypnosis of a forgotten memory.

Dr. R. G. GORDON (Bath) considered that there ight be organic factors which determined the origin d nature of the tic in the psychopathic individual. rticollis, for instance, might originate from muscular eumatism of the trapezius. It was necessary, erefore, to examine the patient carefully for pathogical conditions other than in the nervous system d treat the lesion accordingly.

Dr. N. D. ROYLE (New South Wales) had found ronic arthritis of the cervical vertebræ in association th spasmodic torticollis.

Dr. A. J. BROCK (Edinburgh) agreed fundamentally th the disciplinary method of treatment, but ought that the particular symptom should be less mphasised and more attention paid to the underlying ychical constitution.

Dr. P. C. CLOAKE (Birmingham) said that only one ychic motive for the persistence of tic had been erred to—viz., the satisfaction derived from the easurable sensation obtained from the performance the tic. It was equally important to realise, wever, that in the psyche there were different els of function and ample opportunity for psychic otivations in addition to this.

THURSDAY, JULY 21ST.

The second meeting of this Section was held in njunction with the Section of Mental Diseases. of. EDWIN BRAMWELL again presided, and the bject of discussion was

EPIDEMIC ENCEPHALITIS.

Dr. IVY MCKENZIE (Glasgow) described the history the disease, especially in Glasgow, and also dealt th the epidemiology. From 1918 to 1924, he said, e attention of the profession had been directed to a new disease," accounts of which came from various rts of the world and a description of which had eady been given a year earlier by von Economo in ustria. That it was new admitted now of no estion. An anatomical basis was soon established a non-purulent form of encephalitis which was scovered in every case which came to autopsy. its pathological anatomy encephalitis lethargica fered from other forms of encephalitis in that there s an absence of naked-eye signs of disease in the atral nervous system. In the acute stage the croscopical lesions were diffuse, were of a moderately ute inflammatory character, and tended to be more nounced in the basal ganglia and the substantia gra. In the Parkinsonian syndrome it had been und that the most pronounced lesions were in e substantia nigra. Dr. McKenzie was not conced, however, that the histological appearances sembled those observed in such chronic affections of e central nervous system as syphilis, tuberculosis, laria, or trypanosomiasis. The possibility must be ken into account that the degeneration of the bstantia nigra was not an isolated lesion accountable the clinical phenomena in the sense that anterior rnual degeneration accounts for the paralysis of liomyelitis, or destruction of the motor cortex counts for upper neuron hemiplegia. It was more ely that the Parkinsonian sequelæ were the expresn of a disordered function of the whole comndium of reflexes related to the basal nuclei, the d-brain, and the vestibular apparatus, and concerned with the regulation of those phases of automatic posture which rendered voluntary movement possible. The virus responsible for encephalitis appeared to show a predilection for the great correlating centres of the nervous system—that is, for the grey matter on the afferent side of the proprioceptive system, for certain basal nuclei, and for the posterior cornua of the cord. He suggested, therefore, that the Parkinsonian sequelæ was due to a functional derangement of this system incident to the destruction of some of its vital parts in the early stages of encephalitis.

Dr. J. G. GREENFIELD (London) dealt with the ætiology, clinical pathology, and morbid histology of the disease. He said that the virus responsible for encephalitis lethargica had not yet been identified, and that it was still uncertain if the disease had ever been transmitted to animals. Some workers claimed that the ætiological agent was identical with that of herpes febrilis, differing from it only in possessing a greater affinity for the nervous system. The only serious criticism brought against this theory was that in the few instances in which encephalitis had been caused in rabbits by inoculation of human material, the virus of herpes febrilis had been accidentally included. This might well have been so in Levaditi's first case, in which herpetic vesicles were present at death. In fact, Flexner had obtained an apparently identical virus from the cerebro-spinal fluid of a convalescent case of neurosyphilis. Herpes was a common and widespread disease in man, and the fluid from herpetic vesicles was constantly pathogenic to rabbits. The whole question remained sub judice. The only laboratory examination which gave any assistance in the clinical diagnosis of the disease was that of the cerebro-spinal fluid. In the early stages of the disease this fluid might be quite normal or might contain a slight excess of glucose, which was of doubtful significance. Usually, in the first few weeks of the disease, however, there was a lymphocytosis of 10 to 100 or even more cells per c.mm. The cells were usually all mononuclear, with occasional polymorphonuclear cells. Excess of protein was exceptional, and a coagulum practically never formed. Not infrequently the colloidal gold reaction gave a curve of the luetic type; paretic curves were much rarer. With regard to the histological picture of the disease, there had been a tendency to focus attention on the mid-brain, forgetting the cerebral cortex. He did not agree with Dr. McKenzie that the lesions were confined to the proprioceptive system, and he showed slides illustrating involvement of the anterior cornual cells of the spinal cord.

Dr. GEORGE RIDDOCH (London) considered the chronic forms of the disease, and maintained that encephalitis lethargica was a chronic malady comparable in its course with neurosyphilis and disseminated sclerosis. An important group of cases was that in which the disease appeared to be chronic from the outset. Although the virus had a predilection for the brain-stem and corpus striatum, no part of the nervous system was immune. With such a widespread infection, classification on rigid anatomical or physiological lines was impracticable. The Parkinsonian syndrome, however, was the most common disability of a general kind in adults resulting from the disease; it might appear rapidly during the acute illness, but more often its evolution was slow and progressive, although in its course there might be stationary periods. As the clinical picture in its fully developed form was so familiar, Dr. Riddoch confined his observations to milder forms of Parkinsonism. In its minimal development there was slight fixity of the facial expression and of the eyes, a tendency to hold the head still, and a diminution in the natural fidgetiness of the healthy individual.

Dr. Riddoch next dealt with the various involuntary movements—choreiform movements, bradykinesia, myoclonic movements and tremors, muscular atrophy, and spastic paraplegia—that might result from the disease. He also described the forms of respiratory disorder and the endocrine involvements—as shown

by adiposity, diabetes insipidus, &c.—that might occur. Finally, he mentioned a clinical picture of chronic encephalitis lethargica termed the "asthenic syndrome," of which enfeeblement was the constant and main symptom, and in which the physical signs might be slight.

Dr. R. M. MARSHALL (Glasgow) dealt mainly with the mental aspects of encephalitis lethargica. Age, he stated, appeared to play an important part in the incidence of the residua and sequelæ of the disease. Psychomotor excitement, with or without nocturnal wakefulness, and somnolence in day-time, choreiform movements, and disorders of respiratory rhythm all showed a preference for the early years of life. On the other hand, the Parkinsonian syndrome, melancholia, confusion, and residual palsies, were the appanages of youth and adult life. Much attention had been paid to the moral aspect of the behaviour of the restless, naughty child, but very little had been said about the maniacal character of his misbehaviour. There was nothing cunning or underhand about the misdemeanours of these children; unlike delinquents, they did not choose a convenient season in which to commit misdeeds; they carried them out in the public eye. In brief, there was much instability and little or no evidence of moral depravity.

Prof. R. CRUCHET (Bordeaux) maintained that slowness of movement (bradykinesia) in post-encephalitic states was quite independent of muscular hypertonus. He also showed graphs illustrating the increase in the muscular relaxation-time in cases of hypertonia, together with others demonstrating the greatly decreased relaxation-time following the injection of scopolamin.

Prof. G. C. GUILLAIN (Paris) described several cases in which the patients complained of symptoms that at first appeared to be those of myasthenia gravis. Subsequent investigation showed the cases to be examples of post-encephalitic disorders, a fact which emphasised the importance of fully investigating the physical signs and history in all cases of apparent myasthenia and neurasthenia.

Dr. EDWARD MAPOTHER (London) drew attention to the fact that many cases of post-encephalitic states might be missed if attention were focused only upon the psychological aspects. The severity or otherwise of the acute phases bore little or no relation to the development of mental symptoms. Also, the intensity of mental symptoms was quite independent of the degree of physical disability.

Dr. B. SACHS (New York) had found that ocular manifestations were usually the first signs of the disease. Not a few cases, however, might begin with an apoplectiform seizure. He thought the term "central and basilar encephalitis" was a better designation of the disease than "encephalitis lethargica."

Dr. W. A. POTTS (Birmingham) regarded the disease as chronic, specific, and progressive. He had met with Parkinsonian cases alternating between euphoria and depression. As regards treatment, Dr. Potts stated that he had seen good results even in chronic cases following the use of autogenous vaccines, the latter being made from organisms obtained from the nose and throat. Prolonged Plombière's treatment was also of value.

Prof. KARL PETREN (Sweden) called attention to the value of the nasopalpebral reflex of Guillain in the diagnosis of Parkinsonism. This consisted in the exaggeration of blinking of the eyelids elicited in tapping the skin about the root of the nose. In Prof. Petren's experience, the interval between the onset of encephalitis lethargica and the development of a Parkinsonian syndrome had never been longer than four years; it was a question of great practical importance to determine how long this interval could be, and if others had had the same experience as he.

Dr. N. G. ROYLE (New South Wales) gave a cinematograph demonstration of two cases of Parkinsonism in which posterior sympathetic ramisectomy had been performed. The films showed the condition of the patients before and after operation, improvement being very striking.

Dr. J. M. WOLFSOHN (San Francisco) said that it had been his experience that few acute cases of the disease passed into a chronic stage if six months' complete freedom from mental and physical fatigue were insisted upon. The management of an acute case included complete rest, intestinal antisepsis, and the administration of polyvalent autogenous vaccines made from intestinal and nasopharyngeal organisms.

Dr. T. A. ROSS (Penshurst) emphasised the importance of a full and accurate history if many cases of neuroses were to be distinguished from encephalitis lethargica.

Dr. POSTON (Oldham) described a case with involvement of ocular muscles, the eyeballs being ordinarily immobile. Following the syringing of the ears with cold water the patient was able to move his eyes temporarily in all directions.

Dr. P. C. CLOAKE (Birmingham) considered that the mental symptoms of encephalitis lethargica were those of a toxi-infective type, and resembled in some ways the acute mental effects of toxins such as alcohol. He thought the mental changes could best be understood by regarding mental and nervous phenomena as evidences of orderly evolution and distribution of energy derived from neuron activity at different levels in the nervous system.

SECTION OF DERMATOLOGY.

THURSDAY, JULY 21ST.

THIS Section met under the chairmanship of Dr. R. CRANSTON LOW (Edinburgh).

Dr. S. E. DORE (London) opened a discussion on

THE USES AND LIMITATIONS OF ULTRA-VIOLET RADIATION IN DERMATOLOGY.

He quoted from a paper, written in 1902 by himself jointly with the late Sir Malcolm Morris, the words: "Although in our opinion the results we have obtained have fully justified the employment of the treatment, and in some cases no other treatment could have produced such good results, we do not regard it as the only method to be used in all cases, nor advocate it indiscriminately to the exclusion of other methods." This was still his opinion to-day. After reviewing the history of light treatment and the modifications of the original Finsen lamp, Dr. Dore pointed out the difficulty that modern apparatus had not solved—that is the lack of penetrating power in mercury-vapour and tungsten lamps, and the small area available for concentrated carbon arc rays. He doubted whether many extensive cases of lupus were cured by unaided light treatment. With surgical measures and selective caustics much more rapid results could be obtained. There was no doubt that ultra-violet radiations were an excellent stimulant of hair-growth, but the tendency to spontaneous recovery made it difficult to assess the value of light treatment in alopecia areata. The results seemed to depend, as in lupus, on the intensity of the inflammatory reaction. He had seen extensive psoriasis eruptions clear up under light-baths and relapse during a continuance of the treatment; the majority of cases showed little permanent improvement. It seemed probable that better results would follow strong inflammatory reactions with erythema and desquamation, but in most cases equal benefit could be achieved more quickly by chrysarobin. Improvement in acne vulgaris was chiefly due to exfoliation; the results were not much better than those following keratolytic preparations, and were much worse than those produced by X rays. Light treatment benefited cases of impetigo and staphylococcal infections which failed to yield to antiseptic applications; it was also useful in chronic septic and tuberculous ulcers, and in some acro-asphyxial conditions. The combined local and general use of light, first advocated for lupus by Reyn in 1918, did not invariably produce good results. The biological action of the rays was probably mainly destructive, although in rickets the effect was

scribed to activation of the skin cholesterol. Heat nd fresh air were probable factors in the increase f hæmoglobin and leucocytes. The stimulating effect n operators was very likely due in part to the nhalation of ionised air, and the psychological factor ust not be forgotten. Nor must luminous and heat ys be left out of account, since comparatively few ltra-violet radiations could penetrate the atmosphere. he value of glass transparent to ultra-violet rays as problematical in cities. The basal metabolic te was not raised by actinic light unless cooling air ere also present, and the hardy northerner took ecedence, in health and endurance, of the softer, nbaked, ultra-violet-lighted southerner.

Dr. F. GARDINER (Edinburgh) stressed the psychic fects of ultra-violet therapy, and deprecated its mmercialisation. Its value in rickets was estabshed, but beyond that there was an ever-increasing ea of doubt. We had as yet insufficient data from e physicist and biochemist. Useful additions to the mple lamp were focusing with a quartz lens and plying sufficient pressure to render the part anæmic. tuberculosis of the skin light gave great benefit; casional failures were probably due to the association pulmonary affection with the skin condition. ngating and ulcerated types responded most pidly. Out of 171 cases treated by him since 1924, had been cured and 65 improved. The addition treatment by trichloracetic acid and caustics had ven better healing and good cosmetic results. At esent the carbon arc was the best lamp, and the ercury vapour the least satisfactory. Lupus erythematosis was not one definite disease, but those cases hich were associated with a toxic focus responded light, as did skin diseases associated with general bility. Prurigo in children, but not in adults, as benefited. Light would allay the superficial stulation of sycosis, but the condition might be gravated by light applied by inexperienced workers. oriasis was made worse, but alopecia areata was proved. Varicose and chronic ulcers were palliated, t it was for the Bazin type of ulcer that light was pecially useful. In conclusion, Dr. Gardiner said at the effects of light were systemic, and it could be ed where there was some systemic disturbance; so as a stimulant for certain areas, and to reduce stulation.

Organisation in the Treatment of Lupus.

Dr. W. J. O'DONOVAN (London) reviewed the story of the light department at the London spital. He said that optimism or pessimism wards the problem of lupus depended on how it is tackled: it was a fight needing an organised ily attack. The nodules should be treated night d morning, and the intervening time filled in with neral light baths. It was essential that the patients under control; the public health authority must y their fares, see that they had proper nourishment d so on, and there must be a school within the ht department. In these circumstances the extent the disease need cause no anxiety; the only curable cases were those with lymphatic obstruction the face. The type of patient who had had his uble for 30 years and only came up on the persuasion his friends was better untreated, for he would not tend regularly and would only disgrace the department. Picked cases, however, would give 90 per cent. cures. Among the rare disasters might be mened three deaths during light treatment for fection of the larynx, one suicide, and three cases tuberculous meningitis. Cancer following light eatment had never been seen in all the 26 years' perience of the London Hospital. Psoriasis might temporarily benefited, and, anyway, the course is encouraging to the patient. He had seen cases red by exfoliation—ten minutes of the mercury-pour lamp at 2 feet for a week, and then at 1 foot. xfoliation might also cure acne, but the speaker d seen this complaint develop during a course of ht treatment. As to prurigo, if light comforted ese patients they should have it, and if there was henisation they should have it strong. For the purely psychic case it was as good as any other treatment; the patients appreciated it, and were, at any rate, free from messy ointments. Multiple subcutaneous abscesses in infants might be dispersed by three months of steady light treatment. For septic compound fractures light was extremely useful, lowering fever and promoting healing of sinuses and separation of sequestra.

Prof. J. G. TOMKINSON (Glasgow) related his personal experience of light therapy in lupus and emphasised its psychic value. He characterised it as one of the most useful therapeutic agents of the present century, even if it went no further than clearing up the loathsome features of extensive ulcerating tuberculous lesions.

Dr. T. C. GILCHRIST (Baltimore) quoted the unpublished work of a fellow-countryman who had succeeded in measuring the dosages of ultra-violet rays by the use of lithopane.[1] Much more harm than good had been done by X rays, and there was a danger of the same results following the indiscriminate use of ultra-violet light. More people were extremely sensitive than was recognised; possibly they could be desensitised by small doses. Sunlight, in his opinion, certainly could produce cancer. Other workers had succeeded in obtaining the "border rays" between the X and the ultra-violet, and had had good results from their use in cancer of the skin. The group called "ultra-violet" might be a mass of rays, many of which were not necessary. He suggested an answer to the problem of why hydroa vacciniforme with hæmatoporphyrinuria should be fatal, that the collapse of the blood pressure was a reflex excitation of the medullary centres due to the effect of light on the nerve endings in the skin. Lupus was very rare in America. He stressed the value of diathermy, as the desiccating knife left a sterile partition between the diseased area and the healthy, which the surgeon's knife could never do.

Sir NORMAN WALKER (Edinburgh) recalled the early history of lamp treatment, and said that many of the first patients were wonderfully well to-day. He queried the value of the present-day tendency to get stronger and stronger lamps, and thought it might be better to have longer exposures to rays of less intensity. He agreed with Dr. O'Donovan about the need for organisation in light therapeutics. Very many treatments did lupus good—Unna's old salicylic acid paste was still one of the best. It was essential for the doctor to be an optimist. Perseverance was the first lesson Finsen had taught. X ray treatment led to many deaths, and was only justified in the hands of a real expert. Moreover, there was a chance that it would produce cancer of the skin. There was no doubt that sunlight caused cancer exactly like X ray cancer. It was time to put a brake on the extreme use of light. Early diagnosis was of the greatest importance. He thought that with modern fashions the neck escaped psoriasis more often than it used to. Unfortunately, practitioners had been taught for generations to give a bad prognosis for this condition, but if the patients could be persuaded to persevere to the end very many of them got well.

Dr. H. MACCORMAC said that the claims of light therapy had been exaggerated in some quarters. Results in lupus and psoriasis were variable, and the former seemed to depend in some measure on the place in which the patient got the disease and was treated. Scandinavians were more liable to tuberculous conditions of the skin than other races, and their lesions tended to clear up more readily. In Austria these skin conditions were almost unknown, but cancer was much more common. Of six patients who had had total alopecia for many years, five had almost completely recovered under violet light. Some tabes patients reached a stage where they hung fire; it was then useful to knock off all antisyphilitic treatment for a time and give a course of ultra-violet rays. Marked improvement often followed.

Dr. W. MITCHELL (Bradford) preferred diathermy to any other treatment for lupus; it produced a

[1] See also Amer. Jour. Phys., 1924, i., 49.

soft scar with no pitting. Cases sent up for light treatment as labelled malnutrition should always be investigated for diabetes.

Dr. A. C. ROXBURGH (London) agreed with Dr. Dore's remarks, and commented on the value of ultra-violet light in the diagnosis of ringworm. Fluorescence was seen on the infected hairs through Wood's glass. This method had been found very satisfactory as a test of cure after treatment and as a means of detecting very early infections. General light baths were valuable in tuberculosis of the skin, especially as an adjunct to local caustics. They benefited 50 per cent. of those who could not have sanatorium treatment, but would not take the place of air, good food, and sunlight. There was a certain risk of lighting up a lung infection. Light was very useful for multiple boils, superficial sepsis, unhealed wounds, and a few chronic dermatitis and eczema cases. Locally it benefited alopecia and telangiectasis after X rays. Sycosis might be improved but could not be cured. The spread of alopecia was not affected, and the treatment was of no use for premature baldness. Acne was much better treated by X rays, and the results in psoriasis were no better than those of chrysarobin. Seborrhœic dermatitis was aggravated.

Dr. R. AITKIN (Edinburgh) quoted cases of hypersensitiveness to light, and said that the armlet was of no use for gauging reactions. He had tested artificial silks, but had found no evidence that they let the ultra-violet rays pass.

Dr. HALDIN DAVIS, answering a question from Dr. Aitkin about the use of ultra-violet rays for ringworm, said that he had had cases previously treated in vain with light which cleared up completely with X rays.

Dr. F. D. HOWITT (London) said that artificial light never gave the same results as sunlight, but went some way towards it. It was best for cases, such as alopecia and prurigo, where the sympathetic system was involved, for those where the resistance of the body was reduced by infection, as in syphilis, tuberculosis, acne, sycosis, and lupus, and where the ionic calcium was lowered, as in the catarrhal child. Good results could not be obtained from two or three treatments, and more harm than good was done by large exposures.

Dr. K. RUSSELL (Newcastle) doubted whether there were any difference between the results from real and artificial light—for example, from Leysin and Copenhagen. Many conditions could not be treated by natural light. He had treated ringworm successfully with ultra-violet light.

Dr. W. BROWN (Glasgow) spoke of the need for educating the public, and of the abuse of ultra-violet or so-called violet light in such places as beauty parlours.

Sir ROBERT BOLAM (Newcastle) said that the truth lay between optimism and pessimism, and caution should be the note of the day. He stressed the value of general control and discipline associated with the light treatment of lupus. No one who had seen skin carcinoma in field workers would forget that we were dealing with something a little dangerous in X rays.

Dr. CHRISTINA BARROWMAN spoke of the general improvement and relief from pain effected by ultra-violet light treatment of burns. She had cured very early cases of ringworm in babies with light.

The PRESIDENT rated the danger of carcinoma after X ray treatment of lupus at 50-60 per cent. It would be years before the results of ultra-violet treatment could be known, and it therefore behoved workers to go cautiously. Everybody was experimenting with it; it was for the dermatologists to find out the underlying principles. He suggested that the benefit in lupus was due to the fact that the antibody to tuberculosis was anchored in the skin itself. Possibly all the diseases which gave marked skin reactions were those likely to be benefited by light therapy.

Dr. H. C. G. SEMON (London) read a paper on the

Value of Krysolgan in Lupus Erythematosus.

Reviewing the evidence for and against the tuberculous theory of the ætiology of this condition, he summed up in its favour, and said there was no doubt of th value of gold treatment in some types of cas Krysolgan was an attempt by the firm of Schering t get a non-toxic product. The urine should be teste for albuminuria during treatment, and renal tube culosis was a direct contraindication. Increasir weekly doses of 0·015, 0·15, 0·375 and 0·75 grai should be given. There was no febrile reaction, b stomatitis or dermatitis might occur and there migl sometimes be fleeting pains in the fascial space A focal erythematous reaction indicated a goo prognosis. Of nine cases which Dr. Semon reporte fully, six had been greatly improved, one unimprove German workers had had better results. He calle attention to a high proportion of tuberculous ætiolog in the histories of the successful cases. He conclude that, although the treatment was not free from ris the disease was at least as distressing to the patie as syphilis, in the treatment of which equal risks we taken.

Dr. GILCHRIST pointed out that the same cau could produce widely different clinical appearance Lupus erythematosus cases could be grouped in those which were tuberculous and those which we not. He mentioned three cases cured by radium.

Dr. O'DONOVAN said he had tried krysolgan o seven cases: two were distinctly benefited.

Dr. ROXBURGH had also had seven cases; thr were cured, two much improved, and two unaffecte after 11 doses. It was a very useful treatment, bu only time could show whether its results were pe manent. Many cases could be cleared up temporari by protein shock.

Dr. HALDIN-DAVIS quoted nine cases with tw cures. Others had shown temporary improvemen He gave smaller doses than those indicated by D Semon.

The PRESIDENT remarked on a characteristic sk rash developed by patients treated in the medic wards with sanocrysin. It looked just like lupu erythematosus, but always cleared up.

Dr. G. B. DOWLING (London) read a paper on the

Treatment of Tinea Capitis with Thallium Acetate.

He said that this was a subject which ought to l thoroughly thrashed out. X ray epilation had certa well-known disadvantages. A dose of 8 to 9 mg. p kg. of body-weight of thallium acetate produce satisfactory and complete baldness. Over a thousar cases had been reported from the Continent, and th speaker had tried it on 100 cases during the la three years; ten were still under treatment. On th seventh day the hair loosened, on the fourteenth came out, and depilation was complete on the nin teenth save for some fine lanugo hairs which nev fell and were never attacked by ringworm. General the eyelashes and eyebrows remained, though th outer third might be thinned. Sometimes stump would not fall spontaneously, but brushing brough them out, except on a few occasions, when a fungicid had to be used all over the scalp to protect the ne hairs which soon appeared. Ointment should l rubbed in all over the scalp twice daily from the firs and stumps removed every day. This should l continued for two weeks after all traces of infectio had disappeared. Regrowth generally began with a fortnight. Combination of thallium and X ra did not work, but all the children under 3 treate with thallium alone were cured, as were 35 out of over 3. The toxic effects must not be forgotten only two cases had been entirely free from ther The children were peevish, anorexic, and drows to a very variable extent. In animals the thyro suffered and the children showed hypo- or a-chlo hydria. Small doses of thyroid and hydrochlor acid produced rapid recovery. Very young childre were more tolerant of the drug than older ones, bu none were any the worse for it in the end. There wa no danger of permanent epilation, and the cost wa very slight. The toxic effects and some uncertaint of complete epilation were the only disadvantages.

Prof. J. G. TOMKINSON pointed out how unfortuna it was that epilation was inseparable from the trea

ent. The ideal method would be to anticipate and spel the infection without epilation.

Dr. ROXBURGH described 19 cases treated at St. artholomew's Hospital. Eleven were cured, and ur had not been followed up. He gave 8·5 mg. per g. of body-weight.

Dr. SEMON said he had been using the method nce Dr. Dowling introduced it. No effort should be ared to find some new method of treating this cially serious condition. He had had one failure ly out of 20 cases. He followed up epilation with r. Adamson's ointment (equal parts of sodium loride and vaseline), which produced a superficial lliculitis and brought out the stumps. Thiosulphate soda might prove a useful antidote for the toxic ects.

SECTION OF VENEREAL DISEASES.

FRIDAY, JULY 22ND.

THIS Section met under the presidency of Mr. AVID LEES (Edinburgh), the morning session being voted to

ROUTINE EXAMINATION OF CEREBRO-SPINAL FLUID IN SYPHILIS.

Mr. C. H. MILLS (London) pointed out that upon rly recognition of involvement of the central nervous stem depended much of the subsequent management the syphilitic patient, and the prognosis from a urological point of view. The routine examination the cerebro-spinal fluid was therefore absolutely sential in the management of syphilis at all stages the infection. In the primary stage it was an vantage, in the later stages it was imperative, to ow the condition of the cerebro-spinal fluid before ginning treatment. The initial course of treatment ould be standardised to consist of the administration not less than 4 g. of salvarsan, or the equivalent of osalvarsan plus bismuth and mercury, over a period t exceeding 14 weeks. This course should be looked on as more or less of a therapeutic test, and should followed by re-examination of the cerebro-spinal id within six weeks of the cessation of treatment. the earlier cases this period was, he thought, the ost critical epoch in the career of a syphilitic, since was then that the cerebro-spinal fluid might provide ssibly the first and only indication of invasion of the ntral nervous system. The warning obtained from utine examination at this period should entirely event the subsequent development of meningeal lapses and their sequelæ.

Discussing the importance and significance of the rious tests, Mr. Mills said that the Lange colloidal ld reaction was used in all the frankly neurological ses in his own series, and from ten years' clinical servation of the progress of a considerable number neurosyphilitics he was convinced that a paretic nge curve, accompanied by a persistent positive assermann reaction in the cerebro-spinal fluid, was rong presumptive evidence of parenchymatous volvement of the central nervous system. Revised tensive schemes of treatment should be started at ce in all such cases, thus saving much valuable time. every early case treated *ab initio*, the cerebro-spinal id should be examined, together with a blood assermann test, at the end of the first, second, third, d fifth years. All cases presenting a persistent sitive blood Wassermann reaction, at whatever ge of the infection the patient first came under servation, should have the cerebro-spinal fluid vestigated besides a careful neurological examination. By routine procedure of this kind the disasters endant upon cerebral and spinal endarteritis uld be anticipated and by adequate treatment ey would be entirely prevented. He urged that a utine blood Wassermann test should be made upon ery patient at all medical institutions, irrespective the nature of the complaint, and when this was und to be positive an investigation of the cerebro-inal fluid should follow. Furthermore, once the ebro-spinal fluid had been found to be pathological a syphilitic case, subsequent examination of the fluid was imperative for many years after it had been rendered normal. This regular re-examination was especially indicated in any case which had once relapsed, and in definite cases of neurosyphilis after the fluid had become normal. If lumbar puncture were limited to the cases with obtrusive signs irreparable damage might result, since a low-grade parenchymatous encephalitis, with little or no meningeal involvement, might exist for years with indefinite symptoms impossible to classify or interpret without the aid of spinal fluid tests. On the other hand, certain types of neurosyphilis, including the purely vascular type, gumma unaccompanied by meningitis, some unusual psychoses, and luetic epilepsy were often found with little or no change in the cerebro-spinal fluid. Even in the presence of such negative findings, however, the neurosyphilis could be much benefited by specific treatment.

The earlier treatment was begun the greater was the chance of preventing syphilitic involvement of the central nervous system; the earlier the recognition of such involvement, when it had occurred, the greater the possibility of preventing the invasion of the parenchyma.

Dr. GEORGE RIDDOCH (London) said that no one could question the necessity for examining the cerebro-spinal fluid in the early stages of syphilis. But it was necessary to consider what was the value of positive findings without clinical manifestations of involvement of the central nervous system, and what was the value of negative findings. There was discrepancy in the results of various observers. Mr. Mills had found that 4 per cent. of patients with primary syphilis had a positive Wassermann reaction in the cerebro-spinal fluid, whereas observations at Haslar during the war put the figure at the same stage as 14 per cent. Again, what was the value of a gold sol paretic curve six weeks after infection? Did it mean that paresis would really occur? Very many more findings were required, extending over a greater length of time, before the procedure could be standardised. Would serological examination be required at intervals during the whole life of a man who had once had a positive reaction in the cerebro-spinal fluid? Where tests had been positive and neurosyphilis had developed, the patients were, in Dr. Riddoch's opinion, unsafe for life. It was essential not to lose sight of the patient himself when dealing with his blood and cerebro-spinal fluid. Antisyphilitic drugs were poisons, and it was a mistake to chase after a positive Wassermann to the neglect of the patient's general health.

Dr. D. K. HENDERSON (Glasgow) said that there could be no question about the value of lumbar puncture. Who could give the prognosis in a mental case, without all the investigations—Wassermann reaction, globulin estimation, and cell count? Lumbar puncture, however, sometimes caused very severe headaches, and the only way to prevent these was to put the patient to bed for 24 to 36 hours. With the present methods of treatment, we might look forward to less neurosyphilis in the future. Sometimes, said Dr. Henderson, there was no correlation between clinical signs and pathological findings, and it would be wrong to diagnose parenchymatous syphilis on the pathological findings alone, to the patient's relatives. On the other hand, he quoted the case of a woman who in 1922 suffered from general paralysis of the insane, who then improved and was discharged, was readmitted, and was now a typical case of general paralysis of the insane in spite of the fact that all the pathological reports were negative. Again, a typical paralytic had gold sol, Wassermann, and other tests all negative. Clinical cases of several years' standing often reacted better to treatment than earlier and supposedly more favourable cases. He had seen cases in which tabes developed in spite of good intravenous treatment in the early days of the syphilitic infection.

Dr. J. G. GREENFIELD (London), referring to the use of the Kahn precipitation test for cerebro-spinal fluid examination, said that its results compared

favourably with those of the Wassermann reaction, but there was a tendency for the Kahn test to be negative earlier in treatment, while the Wassermann reaction was still weakly positive. Boltz's acetic-anhydride test was specific for general paralysis as distinct from cerebral syphilis. The very purest chemicals must be used and a negative result was of no value. The Kafka colloidal paraffin reaction corresponded closely with the Lange test and the type of curve corresponded better than with the mastic or bezoin reaction. Wu's colour estimation of the actual quantity of protein in general paralysis of the insane was of great value. Wu had used it for the estimation of globulin and protein, and had found that general paralysis of the insane was the only condition in which there was approximation of these substances. There were substances in the blood, said Dr. Greenfield, which inhibited the Wassermann reaction and so prevented the blood from showing as strong a reaction as it should. After treatment by malaria and tryparsamide it might be found that the cerebro-spinal fluid was strongly positive although the patient was apparently cured.

Colonel L. W. HARRISON said that whilst he had every sympathy for Mr. Mills's enthusiasm, he also had sympathy for the patient and perhaps also for the pathologist, particularly in view of the further four tests which Dr. Greenfield had mentioned. A working compromise might perhaps be to test the cerebro-spinal fluid in cases selected according to their behaviour to the first course of treatment. Analysis of the results of treatment in cases of syphilis in males at St. Thomas's Hospital had shown that in a high proportion of sero-positive early cases which were still positive at the end of the first course further treatment, even to the extent of six or seven courses, has not resulted in a reversal of the reactions. In a high proportion of these refractory cases, again, the cerebro-spinal fluid had been found after many courses to be positive. On the other hand, among early cases in which the serum was negative at the end of the first course and in which the patients had remained under regular treatment, he had not yet seen one with a positive cerebro-spinal fluid at the end of the programme of treatment. He thought that the first examination of the cerebro-spinal fluid in early cases might be limited to cases which had not responded with a negative serum reaction to the first or second course of treatment. It seemed preferable to carry out complete examinations on the few fluids likely to be positive than to make necessarily cursory examinations of the multitude; he said this without prejudice to the necessity of examining the cerebro-spinal fluid in all cases before discharge from treatment.

The failure of a proportion of cases to respond to routine treatment had made him think that some means should be sought for changing the tissues so as to make them responsive as soon as the serum reactions were not found negative at the end of the first course of, say, 6 g. of "914" with 4 g. of bismuth (as given at St. Thomas's Hospital). It was perhaps a mistake to go on pushing in more specific remedies in the hope that the spirochæte would be worn out by sheer weight of remedy. Some time ago Major Pettit had reported that at Rochester Row an unresponsive early case had been made responsive by the administration of thyroid, and perhaps by this or some other means the outlook in unresponsive early cases might be changed. Colonel Harrison was convinced that neurosyphilis was less likely to develop later if arsenobenzol was employed simultaneously with another metal (mercury or bismuth). In his own clinic the simultaneous method of treatment of early cases had never been followed or attended by cranial palsy.

Mr. VOGES (Edinburgh) read a paper on new tests useful in examination of the blood and cerebro-spinal fluid. The test depended on the use of colloidal gum benzoin, and in Mr. Voges's opinion it was easier to carry out than the colloidal gold reaction, and secured results very comparable.

In the course of the subsequent discussion,

Dr. FREELAND SMITH (Boston, U.S.A.) spoke of th necessity for painless spinal puncture. He believe that headaches after lumbar puncture were due t hypotension, but were not necessarily the result using a big needle.

Mr. DUNCAN LEES (Edinburgh) described himse as optimistic about modern forms of treatment. E showed cases of tabes and general paralysis of th insane in juveniles, and some adult cases of gener paralysis of the insane and of tabo-paresis, in most which there had been marked improvement wit malaria. He believed that malarial treatment present had a better effect than anything else on th mental condition in these cases, though often th serological reaction was very slow in showin improvement.

Dr. LAURA STEWART SANDEMAN (Aberdeen) sai that she was struck by the interference of syphil with endocrine function, causing in some cas amenorrhœa. Administration of thyroid might som times restore the system to normal and help th patient to get benefit from antisyphilitic treatment.

Dr. MARGARET RORKE (London) said that moder text-books stressed the need for frequent lumba punctures in the treatment of syphilis. Dr. Riddoc had rightly referred to the human element in treatin patients, and she would like to have some guidanc as to how often it would be considered necessary t examine the spinal fluid in women under the followin conditions: (*a*) in the event of all findings bein negative early in treatment, and the patient attendin regularly and receiving all the treatment considere necessary; (*b*) in cases where there has been a positiv Wassermann reaction in the cerebro-spinal fluid an pleocytosis at one time, which had later becom negative on treatment, and where there had neve been clinical signs of involvement.

Mr. MILLS, in his reply, laid emphasis on th necessity for cerebro-spinal fluid examinations in a cases of syphilis, beginning early. He thought tha when a minimum of 4 g. of "606," or an equivalen amount of "914," together with mercury, had bee given, it was desirable to test the cerebro-spinal flui six weeks later, which was a critical and importan time. If this test was negative there was no need t repeat it for at least a year. If the cerebro-spina fluid had once been positive, a specimen of fluid shoul be taken after each follow-on course.

GONOCOCCAL VACCINES.

In the afternoon of the same day a paper on th Employment of Certain Constituents of the Gonococcu in Treatment and of Other Constituents in Test of Cure was given by Major E. C. LAMBKIN (R.A.M.C. and Major LYN DIMOND (R.A.M.C.). For the las two years, they had been endeavouring, at th Royal Herbert Hospital, Woolwich, to elaborat a line of treatment of gonorrhœa in the male b intensive immunising methods. The aims of th treatment were: (1) to raise the immunity of th mucosa through which the organism entered th body; (2) to raise the resistance of the particula glands and organs susceptible to attack by th gonococcus; (3) to raise the antibacterial propertie of the blood and tissue fluids in order to minimis the risk of systemic spread of the infection; (4) t bring the patient under certain precise biochemica and colloid-chemical conditions which had bee found to give optimal results as regarded defenc against the invading organism and to place th infecting organism under conditions in which i was least able to withstand the defence mechanism of the body; and (5) to provide a test of cure. Thes objectives had been sought in the following ways (1) Thorough drainage of the whole urethra by mil irrigating fluids. (2) Maintenance of the patient' urine reaction at a pH of 7·2 to 7·4. (3) Intra urethral instillation of a product of gonococca metabolism, referred to as "exotoxin." (4) Paren teral administration of this exotoxin. (5) Instillatio into the urethra of another gonococcal product

referred to as "endotoxin." The procedure advocated for drainage was posterior irrigation, carried out by the patient, with a solution of potassium permanganate 1 in 20,000. The hydrogen-ion concentration of the urine within the desired limits was effected by the oral administration of large doses of disodium monohydrogen phosphate, averaging gr. 240 four times a day. The reaction was determined roughly by daily titrations of the urine.

Gonococcal Exotoxin.—By special cultural methods it was found that when gonococci were grown on a medium rich in animal nucleoprotein, approximately one-third of the isolated strains developed polar bodies which could be demonstrated histologically by staining methods identical with those employed in the case of *Corynebacterium diphtheriæ*. The polar bodies were composed of alpha-nucleoprotein and beta-nucleohiston, and clinical experiments had shown that both these, especially beta-nucleohiston, were antigenic and relatively non-toxic. Separation of the polar bodies was effected either by the employment of human serum or with 2 per cent. saline solution, the former being the least wasteful method. For intra-urethral use the saline or serum washes were standardised so that the nucleoprotein of 500,000 million organisms was contained in 15 c.cm. To this was added 5 per cent. sodium taurocholate and the reaction brought to a pH of 7·2. For intradermal, subcutaneous, and intramuscular administration the same serum or 2 per cent. salt emulsion of polar bodies or their products was used, but standardised to represent 1000 million per c.cm.

Gonococcal Endotoxin.—To prepare this strains were used which did not throw out the polar bodies employed in the exotoxin preparations—i.e., roughly about 66 per cent. of those isolated. The culture after treatment yielded a product of albumoses which was made up to a strength representing the product of 250 million gonococci in 1 c.cm., the diluent being chemically prepared colloidal silon. The effect of an intraurethral injection being to produce in a quiescent gonococcus carrier a temporary activity, with the appearance of gonococci in the urethral discharge, the endotoxin used in this way acted as a test of cure, but was also used in certain cases to stimulate a reaction in the course of treatment.

With regard to the clinical application of the treatment the speakers said that as soon as a case was diagnosed routine local treatment was begun, consisting of irrigation, followed by an intraurethral instillation of exotoxin which the patient was instructed to retain as long as possible. At the same time intradermal and intramuscular injections of the vaccine were given, each with an initial dose of 0·2 c.cm., or 200 million gonococci. In an average case the injections were repeated at ten-day intervals, the intramuscular dose being gradually increased. The intraurethral instillation was repeated as soon as the pH of the urine became optimal, and subsequently, whenever urethral smears showed the presence of gonococci, throughout the course of the disease. When a cure was clinically obtained, an intraurethral injection of 1 c.cm. of endotoxin was given. If no relapse then occurred after seven days' observation the patient was allowed to leave hospital.

In the last part of their paper Major Lambkin and Major Dimond referred to the question of polar body production in organisms other than the gonococcus—e.g., in tubercle bacilli (bovine), staphylococci, streptococci, pneumococci, and *Bacillus influenzæ*. As in the case of the gonococcus, if vaccines had been cultured upon media providing for detoxication during the period of subculture, and if means were taken during the process of manufacture of the vaccine to prevent further development of toxin, it was noteworthy that there was a complete absence of the negative phase following the administration of such vaccine, as compared with the marked negative phase resulting from vaccines prepared from strains which did not produce polar bodies. They suggested the possibility that in administration of vaccines the negative phase might be due to the liberation of endotoxin from the early digestion of the cytoplasm of the organism, the positive phase occurring later as a result of the liberation of the antigenic complexes present in the polar body fraction of the organism. If this was a true explanation, the negative phase occurring as a result of vaccine administration did not appear to be necessary to the development of the ameliorative positive phase—a conclusion which was confirmed by the fact that it was possible with properly detoxicated polar body producing strains of all organisms to bring about immediate positive phases with clinical improvement. This had been their experience after 18 months' employment of the toxin-free gonococcal vaccine, provided every precaution was taken against the elaboration of endotoxin during manufacture.

Colonel HARRISON said that early publication of a method involved a risk that, if it did not fulfil the hopes at first entertained, some discredit might fall on the authors. He wished, therefore, to say that he had induced Major Lambkin and Major Dimond to publish their work though they themselves regarded it as too immature. He wanted to increase the number of workers in this new line of vaccine therapy. The workers in his department at St. Thomas's Hospital had reached the productive stage so recently that he could not yet say much about results. Dr. J. O. Oliver had inoculated a number of non-gonococcal subjects, and had found that the complement fixation reaction of their sera was raised from negative to strongly positive by only three injections of the vaccine, so that it appeared to be antigenic. There had been one brilliant result in a case of gonorrhœa which cleared up in a few days and had so far not relapsed in spite of attempts to provoke a return. The other cases treated on the Lambkin-Dimond plan had behaved much as the average of the Woolwich cases. In all of them the discharge had ceased more quickly than usual though there had been some relapses.

The PRESIDENT said that he had long felt that gonococcal infection must be approached through the blood stream as well as locally.

Major LAMBKIN, in the course of his reply, said that probably any polyvalent vaccine was a toxic vaccine.

The PRESIDENT (Mr. DAVID LEES) then opened a discussion on

THE PLACE OF BISMUTH IN THE TREATMENT OF SYPHILIS.

He began by summarising the observations he had made on the treatment of over 6000 cases with bismuth. In some of these cases bismuth was the only drug used; in others it was used in combination with drugs of the arsenobenzol series and with tryparsamide; in others, again, it was administered with mercury and some form of iodide. A large number of different bismuth preparations were available, but the preparation which, in Mr. Lees's view, gave the most consistently good results with the least likelihood of upsetting the patient was one of insoluble bismuth in a very fine suspension in isotonic glucose solution, given intramuscularly. Administered in this way the injections were remarkably free from pain and from toxic side-effects, and in this respect bismuth was better tolerated than either arsenic or mercury. Although bismuth was more rapid than mercury in its destructive action on the *Spirochæta pallida* in vivo, it was not so rapid as the salvarsan group of drugs. After the administration of a potent dose of an arsenobenzol product, a living spirochæte could rarely be found 24 hours later in the surface lesion, whereas after a potent therapeutic dose of almost any bismuth preparation spirochætes could often be demonstrated for three or four days subsequently. In its effect on the surface lesions of syphilis in all stages, however, bismuth was almost as efficient as the salvarsan preparations, and was much more rapid than any of the mercurial preparations. In three of his own cases, each of which was in the nature of a hypertrophic papular syphilide of a recurrent type, the administration of bismuth rapidly cleared up the eruption when arsenic in one case, and arsenic and mercury in combination in the two others, had previously failed to do so. The effect of bismuth on the serological reactions in all stages of syphilis was less marked

than that of the arsenobenzols, but more marked than that of mercury.

Mr. Lees was firmly of opinion that in the treatment of syphilis in all its stages, except possibly in pregnancy, it was advisable to administer arsenic and bismuth together rather than separately. The joint administration of these drugs was comparatively safe and was well tolerated, while the results in the large majority of cases were highly satisfactory. Other advantages in the use of bismuth were that it was peculiarly effective and safe in most of the cases which showed intolerance to the arsenicals and to mercury; that in some cases of neurosyphilis and congenital syphilis it apparently gave better results than either arsenic or mercury in clearing up the symptoms and signs of disease; and that it was also undoubtedly a safer means of treatment of any patient with advanced organic disease, whether the latter were due to, or was intercurrent with, syphilis. It was important, however, in his view, that in every case of syphilis in its earlier stages a combination of either arsenic or bismuth, or arsenic and mercury, should be given, and that this combination should be continued up to the point of tolerance until both the clinical and the serological manifestations were cleared up. In the subsequent period of treatment he thought both drugs should still be continued, but the amount of the arsenical drug might then be conveniently lessened, with a view to avoiding intolerance. In any case, apart from cases of intolerance to other drugs, bismuth, valuable as it was, was only an adjuvant to the treatment of syphilis, and should not be used alone, even in the very earliest cases of infection.

Dr. J. C. BUCKLEY (Nottingham) considered the introduction of bismuth in treatment of syphilis second only in importance to the discovery of the arsenobenzols. In one case of his, that of a boy with interstitial keratitis, the condition grew worse after 5·5 g. of novarsenobenzol. Then intramuscular bismuth was given, and improvement took place quickly. The practice of giving the drugs separately, one after the other, as advised in America, had not worked well in his clinic. Dosage was a difficulty; in his experience a blue line occurred on the gum after 2 to 3 g. of bismuth.

Dr. MARY MACNICOL (Edinburgh) regarded bismuth as only an adjuvant to the arsenobenzols, but would certainly give it second place in treatment and relegate mercury to third place. She had found it useful where the Wassermann reaction remained positive after prolonged courses of novarsenobenzol and mercury. She had found that cases of congenital syphilis while clearing up well clinically on arsenic and mercury kept a positive Wassermann reaction until bismuth was exhibited.

Colonel E. T. BURKE (Manchester) said that in his view bismuth was only second in value to arsenobenzol, and was far superior to mercury. For more than two years he had entirely discarded the use of mercury except in those comparatively rare cases which exhibited an absolute intolerance to every arsenical preparation. In such cases, however, bismuth was used instead of arsenic in conjunction with the mercury. He agreed with Mr. Lees that bismuth should not be employed as a substitute for arsenobenzol in the average routine case, but rather as a reinforcement. He believed, however, that these two highly spirochæticidal drugs should not be administered concurrently, owing to a very real danger either that the tissues of the patient might refuse to produce the lethal toxalbumin in sufficient quantity, or that the *Spirochæta pallida* might acquire a resistance to the action of the toxalbumin. With regard to both arsenic and bismuth therapy, it was essential to bear in mind that the curative agent was produced by the tissues into which the element had been introduced, the blood being merely the distributor of the toxalbumin produced by the tissues. The fact that arsenic and bismuth belonged to the same group in the periodic table might be significant; there was a possibility that one might have a neutralising effect upon the other. So far as he could judge, it was more scientific to give arsenic and bismuth in alternate courses, since in this way the spirochæte was not allowed time to develop an immunity to either. Another valuable property possessed by bismuth was its effect upon syphilitic lesions of the circulatory mechanism of an organ. It was not unusual to see cases in which the administration of arsenobenzol for syphilitic involvement of the coronary arteries had brought about such rapid healing that the vessels became sclerosed so quickly as to prevent compensations. In syphilitic, coronary, and aortic root disease it was wise to withhold arsenobenzol and to begin with a prolonged attack with bismuth, or even, if the involvement was very severe, to continue with bismuth alone. It was, he thought, a sound general principle to withhold arsenobenzol in the presence of an acute syphilitic process in an important organ until the virulence had been considerably reduced with bismuth. For the same reason in newly born syphilitic children he began with bismuth inunctions, the preparation used being suspensol bismuth cream, in which the element was in its colloidal form. So far the results appeared to be immeasurably better than with mercury and as good as with arsenic. He had also found bismuth of great use in the treatment of interstitial keratitis, arsenic being administered only after the eye condition had cleared up.

Dr. W. R. SNODGRASS (Glasgow) said that his experience with some 2000 cases of syphilis led him to agree in the main with the conclusions of Mr. Lees. Bismuth had, however, only been on trial for five years, and the ideal preparation for use had not yet been determined. From his own personal experience he agreed that for general use metallic bismuth in isotonic glucose solution was undoubtedly the most satisfactory preparation so far available. All the resources of modern chemotherapy should now be employed to determine whether the best results would come from attempts to increase the tolerance of the body to metallic bismuth, or from the manufacture of some chemotherapeutic drug which would give an enhanced effect. A systematic attempt had been made during the last three years to synthesise a product more active than the metal, but although three drugs had been found to give good clinical results—bismuth gluconic acid, bismuthyl saccharic acid, and the sodium salt of bismuthyl saccharic acid—they had so far failed to improve on the metal. Other lines of research might also be followed—e.g., the pharmacology and toxicology of bismuth, its spirochæticidal action, its effect on the immunity of the body, and its toxic effects. The quantity of a standard bismuth preparation necessary to effect and maintain a clinical and serological cure might be carefully worked out. The time-factor was also of great importance. No final conclusions could as yet be drawn about bismuth, and caution was needed in regard to the criteria of cure. Further serological work might alter the points of view. Up to the present he had noted serological relapses and the development of neurosyphilis during treatment with bismuth. He employed the drug in combination with salvarsan or its substitutes, and/or iodides given either orally or intravenously. He also used it extensively in periods intervening between other drugs. In only a few cases of latent syphilis nothing but bismuth had been employed throughout an extensive period of time, these cases so far having yielded equivocal results. He thought bismuth was most helpful in cardiovascular syphilis, neurosyphilis, visceral syphilis in the absence of massive gummata, syphilis in debilitated individuals, and in those who had some concomitant degenerative process, or some coexisting subacute infective condition. No case of syphilis treated by bismuth at the clinic of the Western Infirmary of Glasgow had yet been discharged.

Colonel HARRISON said that there was a danger that a greater therapeutic power might be attributed to bismuth than it really possessed; in early cases its use to the exclusion of arsenobenzol might easily

esult in the patient remaining infective unnecessarily ong. He therefore felt critical, though bismuth was eing used at St. Thomas's Hospital almost exclu-ively in place of mercury. More work was certainly eeded, in particular to determine the best dosage nd the best chemical compounds. Experiment indi-ated that bismuth either restrained the spirochætes rom developing or prevented the tissues from eacting. There was quite a lot of work to show that ismuth destroyed the spirochætes in the tissues, ut judgment should at present be suspended. ismuth seemed to be better tolerated than mercury, ut it was well to remember that there were other igns of intolerance than stomatitis and albuminuria. ome patients complained of curious aches and pains ; hese might easily be attributed to any other cause han metallic poisoning, but they came to an end when he remedy was stopped and sodium thiosulphate was dministered. Another toxic effect was colitis, hich had been clearly due to bismuth in one of his ases. Although bismuth did not seem to irritate he skin unduly, he had seen at least one case in hich it lit up a dermatitis in a patient who had ormerly suffered from this complaint following rsenobenzol treatment. Nevertheless, he liked ismuth particularly well for the treatment of neuro-yphilis and of cardiovascular syphilis, and also n cases where he thought that enough arsenobenzol ad been administered and where he wanted to give hat Dr. Burke had described as an arsenobenzol oliday. He did not agree with Dr. Burke in relying ntirely on bismuth in cardiovascular syphilis. Whilst dmitting that such cases—particularly those of nyocarditis—required great care in the administration f arsenobenzol, he had found that such a remedy s sulfarsenol, in very small doses twice weekly, ave good results in severe syphilitic myocarditis.

Discussing the comparative effect of bismuth and ercury on the serum reactions, Colonel Harrison escribed two series of sero-positive, primary, and early econdary (up to and including the lenticulo-papular age) cases, both of which received about the same nount of arsenobenzol (5 g. of "914" in not less han four months). In addition to this the mercurial eries received not less than gr. 6 of mercury by ntramuscular injection, and the bismuth series received n average of 3·6 g. per case. The serological results ere as follows :—

N.A.B. + Mercury Series : 158 *Cases.*

15·8	per cent. were	+ + or +	at end of course.
8·8	,, ,,	doubtful	,, ,, ,,
75·3	,, ,,	negative	,, ,, ,,

N.A.B. + Bismuth Series : 124 *Cases.*

12·1	per cent. were	+ + or +	at end of course.
15·3	,, ,,	doubtful	,, ,, ,,
72·6	,, ,,	negative	,, ,, ,,

From this it would be seen that although there ere fewer frankly positive reactions at the end of the ourse in the bismuth series, there were also fewer eanly negative ones. The comparison was not rictly fair, but the cases were as nearly as possible exactly the same stages in both series ; these stages ere quite susceptible to treatment, and the amount arsenobenzol in both series was the same.

Dr. STOPFORD TAYLOR (Liverpool) said that it was xtraordinary that a drug like bismuth should roduce toxic reactions. He had had one patient ho was given arsenic and bismuth and developed iarrhœa, a morbilliform rash, and gingivitis. On opping the bismuth the condition had cleared up. e did not believe that the blue line on the gums ontraindicated administration of bismuth, provided ilton or some similar gargle were given.

Dr. W. H. BROWN (Glasgow) wondered if cutaneous uptions during administration of bismuth might e due to retained depots of bismuth, causing a sort sensitisation. He considered that arsenic followed y bismuth, but not the two together, was the ideal ethod of medication.

Reviews and Notices of Books.

JERVIS ON CORONERS.

Seventh edition. Edited by F. DANFORD THOMAS, Barrister-at-Law, Coroner for the Liberty of the Tower of London. With an historical introduction by F. J. WALDO, M.A., M.D., Coroner of the City of London and Borough of Southwark. London: Sweet and Maxwell. 1927. Pp. xvi. and 364. £1 1*s*.

HIS brother coroners will give a warm welcome to Mr. Danford Thomas's new edition of "Jervis on Coroners," first published by Sir John Jervis nearly a century ago and last revised in 1898. Dr. F. J. Waldo's historical introduction is accurate and in every way admirable. Mr. Danford Thomas has collated the various Acts, rules, and orders, and has added explanatory notes judiciously. He has, for example, an excellent summary of what coroners call "no inquest cases"—cases now governed by Section 21 of the Act of last year. These are explained to be of two classes. The first comprises those deaths where no post-mortem examination is ordered, the medical attendant of the deceased giving the certificate of the cause of death with the coroner's permission. In this class come sudden deaths in the street or in a public conveyance or hotel where medical knowledge of the deceased during life provides a natural cause of death ; deaths in private houses where the doctor in regular attendance may not have seen the patient recently, perhaps through absence on holiday of doctor or patient ; and deaths in mental institutions or in those cases which must be reported to the coroner in accordance with law. Here the coroner, after full inquiry by his own officer, may—if he is satisfied that there are no circumstances of suspicion—signify to the doctor that he sees no objection to the certificate of the cause of death being given as the latter suggests. The coroner then sends the "pink form A" to the registrar, who thus becomes aware that the coroner has been informed of the death. The second class of "no inquest cases" is that in which a post-mortem examination is ordered under Section 21, and the coroner sends the registrar (upon the "pink form B") the cause of death as disclosed by the report of the examination. Here, as Mr. Danford Thomas rightly remarks, a grave responsibility is thrown upon the coroner, who will doubtless make careful inquiries through his officer of all the circumstances, and who will have familiarised himself with the character, attainments, and reputation of the medical practitioners of his district.

Other passages in which the learned editor has made helpful comments are those dealing with medical privilege, deaths under medical treatment, and deaths from or under an anæsthetic. A valuable feature of the book is the collection of Home Office circulars which contain much that the medical profession—if not, indeed, also the general public—is entitled to know. The recent statutory rules and orders appear to be printed *in toto*, though the Orders in Council of July 25th (which bring to an end the Admiralty coronership and the royal right of appointment in the Isle of Wight) were issued too late to be included. The Cremation Regulations of last May, which have their place in the network of arrangements to prevent foul play being undiscovered, seem not to be prominently mentioned and explained as part of the new machinery ; but they are referred to in a separate passage dealing with cremation. If so small a point may be mentioned, the chapter number of the Burial of Drowned Persons Act of 1808 might preferably be printed as 48 Geo. 3 c. 75 rather than as c. lxxv., which suggests a local Act ; and in connexion with this statute it might be worth while to explain that the overseers are now abolished and their powers transferred elsewhere. But these are trivial matters hardly to be named where there is so much to praise. Nor should a review of the new "Jervis on Coroners"

appear in the pages of THE LANCET without a reference to the frontispiece, which shows Thomas Wakley, M.P., coroner for West Middlesex from 1838 to 1862 and founder of this journal, holding a parish inquest, with Charles Dickens (who occasionally attended his courts) standing by his side.

SCIENTIFIC NUTRITION IN INFANCY AND EARLY CHILDHOOD.

By STAFFORD MCLEAN, M.D., and HELEN L. FALES, B.S. New York. Philadelphia and New York: Lea and Febiger. 1927. Pp. 404. $3.

THE authors of this book have made a worthy contribution to an important side of literature. They have succeeded in combining a scientific treatise on the physiology of nutrition in the young, with a lucid and comparatively simple account of the various methods by which the physiological principles can be applied. The greater part of the book is devoted to the normal child or to minor disturbances, marasmus being treated rather shortly. The point of view that is held and stressed by the authors is that the calorie requirements of undernourished children are higher than those of the normal; they advocate a larger allowance of nourishment than is frequently given, and they attribute the success obtained by concentrated feeds such as butter-flour to the psychology of the pediatrist, who habitually prescribes them in amounts which give a higher calorie intake than they would offer in simple dilutions. The last part of the book deals with some digestive disturbances and the chemical pathology underlying them. The account of cœliac disease differs in some respects from that accepted by most English pediatrists. The authors recognise two types of cases: (1) those who are allergic to cow's milk and merely require its withdrawal, and (2) those who show intolerance to carbohydrate rather than to fat, the last type comprising the majority. A useful compendium contains numerous details of calorie values and feeding formulæ.

PHYSICS.

A Short History of Physics. By H. BUCKLEY, M.Sc., F. Inst. P., Hon. Secretary of the National Illumination Committee of Great Britain; Assistant in the Photometry Division of the National Physical Laboratory. London: Methuen and Co., Ltd. 1927. Pp. 263. 7*s.* 6*d.*

IT is 50 years since a book on these lines was attempted and the time is opportune for such a historical survey. The author is to be congratulated on the clever way he has arranged that the sequence of his subject matter fits into the chronological order of scientific facts. This arrangement has been so successfully accomplished that, although the reader passes in successive chapters through the Corpuscular and Wave Theories of Light the Atomic Theory of Matter, the Elastic Solid Theory of Light Magnetism and Electricity, and so on, he nevertheless feels an orderly sequence running through the whole text. The book is attractively written, with numerous quotations from the classics of scientific method. It is not complicated by mathematics, but sufficient references are to be found to original works dealing with this aspect of the subject. The book should be widely read, for the work is admirably done.

Spectroscopy. Third edition. By E. C. C. BALY, C.B.E., M.Sc., F.R.S., Grant Professor of Inorganic Chemistry in the University of Liverpool, Fellow of University College, London. In four volumes. Vol. II. London: Longmans and Co. 1927. Pp. 398. 18*s.*

WHEN the first volume of Prof. Baly's work appeared it was stated that the subject would be completed in Vol. II. We are now told that Vol. III. and Vol. IV. will follow. If, however, the subject is treated in Vol. III. in the same detail as in Vol. II. a continuance of this geometrical progression must be anticipated. The volume under review contains only five chapters—one on interference methods one running into no less than 123 pages on method of illumination, and one on the nature of spectra fluorescence and phosphorescence, and the photography of the spectrum. The work should prove an invaluable reference book; it keeps up the high level expected of the author who does not seem daunted by the vista of work before him.

The Mechanics of the Atom. By MAX BORN Professor in the University of Göttingen. Translated by J. W. FISHER, B.Sc., Ph.D., and revised by D. R. HARTREE, Ph.D. London: G. Bell and Sons, Ltd. 1927. Pp. 317. 18*s.*

THIS book may be looked upon as a counterpart to "The Structure of the Atom," by Prof. Andrade, who is the editor of this, the second book of the series of "International Text-books of Exact Science." Whereas in Prof. Andrade's book the purely physical aspect of the subject was insisted upon throughout, in this book the approach is rather from the mathematical side. This is inevitable where different types of motion have to be scrutinised, perhaps invented, to see to what extent they can satisfy the phenomena which appear when atomic structures are put into motion. The outstanding problem to be solved is the nature of the motion that the atom in its component parts must have to account for all the varied phenomena which have been revealed in the last 25 years. We hardly know which most to admire, the ingenuity of those who have devised experiments to glean the facts or the subtlety of suggestion underlying the efforts of the mathematician to explain the phenomena observed. This book gives a good idea of the range of this side of the work, and should be studied by those whose knowledge of mathematics is fairly advanced.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE, August.—Three articles of some importance appear in this issue of the journal. The first deals with the occurrence of tuberculous silicosis among granite workers in United States. Dr. W. McFarland, the writer, is a medical officer and writes with intimate knowledge of the industry and of the condition induced by exposure to dust among the men; about one-third of the granite is composed of quartz or silica. The article is illustrated by eight good X ray pictures. Dis agreement is stated with the thought that tuberculous silicosis is less infectious than ordinary pulmonary tuberculosis. The second article, which comes from the Harvard School of Public Health, is in continuation of prolonged research into the toxicology of zinc, and deals with threshold doses which will cause metal-fume fever or brassfounders' ague. A formula is arrived at for expressing these threshold doses of zinc oxide. No cumulative pathological condition seems to follow long industrial exposure to zinc fumes. The third and longest article is concerned with the manufacture of electric accumulators and with risk therefrom of lead poisoning. The author is Dr. A. Hamilton, who has inspected the industry in America, in Great Britain, and in Germany; she describes and contrasts the technical processes involved and the risk in the different countries arising from inhaling dust of oxides of lead. The risk can be avoided by care and forethought, which is exerted in Europe through enforcement of regulations by skilled inspectors. In the United States such expert supervision is not yet being exerted, and superexcellent conditions (due to individual initiative) may be found in one factory to be counterbalanced by a shocking lack of all care in another. From this point of view the article is one of great interest.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 10, 1927.

DE OFFICIO CORONATORIS.

THE publication of a new edition of "Jervis on Coroners" is an event not to be passed over in silence. That classic work, which we review on another page, partakes of the immortality and indispensability of the office which it describes. Its present re-issue was made necessary by recent changes in the law—changes so clearly desirable that even an independent legislative body like the Parliament of the Irish Free State has adopted them freely for its own administrative purposes. The new laws are already at work in England, tightening up the machinery for the registration of deaths and protecting the public by more closely supervising the disposal of dead bodies. Minor changes are making themselves felt. Franchise coronerships are beginning to disappear; the Admiralty coroner has been abolished; His Majesty has relinquished his right of appointing a coroner for the Isle of Wight; and the same process will gradually be applied as vacancies occur in the Duchy of Lancaster, which possesses scattered franchises wherever John of Gaunt planted a castle and established an area of peculiar jurisdiction. Amongst other useful administrative provisions which were enacted in the Coroners (Amendment) Act of last year will be recalled the power to accept the verdict of the substantial majority of the jury, the power to invite specially qualified practitioners to make post-mortem and special examinations, the arrangements for avoiding unnecessary inquests and for ending the duplication of criminal investigations when a coroner's court and some other court are pursuing parallel inquiries into the same death.

All these recent changes in the law, which increase rather than restrict the service of the coroner to the community, preserve the continuity of an ancient institution in true British fashion. Coroners were established—or at least their duties were defined—as early as 1194, when they first appear as keepers of the King's pleas. They have shed, it is true, some of their antique functions in the passing of the centuries. They no longer exercise the larger criminal and even civil jurisdiction which was theirs in the Middle Ages. They are no longer concerned with inquiries into the various royal interests in wrecks and sturgeons, the forfeiture of felons' chattels and the confiscation of deodands. Malefactors can no longer take sanctuary in a church; so it is no longer necessary to summon the coroner to parley with them and put them to the choice of either submitting to trial in the courts or undergoing the picturesque alternative of abjuring the realm.

But the chief duty of the coroner remains to-day, as it was in the beginning, the holding of inquests on the bodies of persons who have died by violence or accident or in suspicious circumstances. BRACTON'S famous treatise, transcribed in the apocryphal statute *De Officio Coronatoris* of 1276, laid down that duty in terms which are the foundation of our law to-day. The coroner is to go to the places where any be slain or dead (or where treasure is said to be found) and he is to inquire upon the oath of men of the vicinity if they know where the person was slain, whether it was in any house, field, bed, tavern, or company, and who was present. Likewise it is to be inquired who were culpable and those found culpable are to be taken and delivered to the sheriff and committed to the gaol. Being officers of the King and yet elected by the men of the county, the coroners formed a direct link between Crown and people; they were a check upon the intermediate lords. The coroner's court is essentially the people's court to-day. The neighbours can come and say their say without fear or favour; they play their part in the English scheme of public safety. As is natural in what is essentially a roving inquiry unconfined to narrow issues of the guilt of a particular person arraigned upon a definite charge, the inquest tolerates all kinds of evidence and sifts it for the purpose of the formal accusation which may follow. Presided over with tact and understanding, the court performs an essential service with singular success. As Dr. F. J. WALDO observes in the historical introduction which he has contributed to the latest edition of "Jervis on Coroners," the gradual growth of the coroner's office has beyond doubt made throughout the centuries a considerable contribution to the protection of the lives of our countrymen. We may add that the continued usefulness of that ancient office is a tribute not only to its own merits but to those of the men who have occupied it in the past and who occupy it to-day.

THE BACTERIOPHAGE.

THE phenomenon of bacteriophagy was brought into prominence about ten years ago by F. D'HERELLE, working at the Pasteur Institute in Paris. Credit is therefore due to D'HERELLE for his work and for his persistent attempts to elucidate the mysteries of the phenomenon which is commonly linked with his name. But, as with so many discoveries which break new ground, subsequent delvings into literature have shown that others had explored districts of the new territory and had examined portions of it, though none had succeeded in defining its outlines. F. W. TWORT, in this country, had described an analogous phenomenon which he encountered when engaged in certain researches upon ultramicroscopic viruses, and his name is consequently associated with that of D'HERELLE in descriptions of the phenomenon, although D'HERELLE maintains that the Twort phenomenon is a kindred but distinct one. This view is not shared by many bacteriologists, although few have attempted to reconcile the differences; in the history of pathology both workers are sure of credit. E. HANKIN, as long ago as 1896, discovered an elusive "antiseptic" principle in the water of the Jumna, manifested by its power of destroying many species of bacteria but especially the cholera vibrio; this action was destroyed by boiling, and he attributed it to a volatile body. It is now believed to be an instance of bacteriophagic action. Others noted the occasional occurrence of cultures whose early growth was succeeded by disappearance and dissolution of the organisms, an event which was vaguely dubbed autolysis, but seems to have attracted little attention after it had been named. Many such cases may have been examples of bacteriophagic action. Briefly, the phenomenon consists in the dissolution of bacteria when a substance, known as the bacteriophage, is added to a live culture which, in general, should be young and actively growing. This agent is widely diffused in nature and was discovered by means of an experiment, now classical, in which D'HERELLE added some filtered, and therefore sterile, fæcal material from a patient suffering from bacillary

dysentery to a tube of broth which had been inoculated with the *B. dysenteriæ* Shiga. Instead of showing a growth of the organism the medium after incubation appeared to be sterile. When a quantity of a fresh culture of the bacillus sufficient to produce a visible turbidity was added this disappeared after further incubation and the broth again became clear. D'HERELLE seized upon the idea that he had encountered "a virus pathogenic for the bacterium" and upon this assumption he proceeded to investigate the phenomenon further. Nothing that has happened since has served to shake his faith, and for him the dissolving principle is a living ultramicroscopic virus, a "filtrable organism parasitic of bacteria." The fact, paramount amongst many, which led him to this conclusion, and which has caused such intense interest to be taken in the bacteriophage, is that it becomes regenerated in the course of its action and the phenomenon of solution of the bacteria is capable of unlimited repetition in series. The destructive action can also be demonstrated in surface cultures where, when the active agent is suitably diluted, it produces round areas of bareness in the midst of a flourishing field of bacterial growth; these areas D'HERELLE has designated the "colonies" of the bacteriophage.

From the point of view of the general reader the subject raises at least two interesting questions; one is the real nature of the agent, and the other the possibilities of a practical application of the phenomenon. It is upon the first of these problems that most attention has been lavished and the dispute has been keenly waged without anything approaching general agreement having been reached. D'HERELLE has always stoutly stood for a living organism, abnormal and parasitic towards the bacteria with which it is associated and by means of which its presence is demonstrated. This is a thesis which, in the case of an invisible particle capable of apparent multiplication and regeneration is one not easy to attack, and although the attempts have been many they carry little conviction. The phenomenon has been attributed to autolytic enzymes, to a diseased condition of the bacteria induced by external influences—the "hereditary nutritional vitiation" of Bordet—and to the destructive action of particles of bacterial protoplasm; theories have been propounded by numerous workers with varying modifications, all more or less obscure since they strain mechanistic ideas to account for phenomena which are quite outside the range of common experience with chemical and physical factors. What are the criteria of life? The answer given by D'HERELLE is the possession of the properties of assimilation—the transformation of grass, by the sheep, into "sheep substance"—and adaptation. In the multiplication of the bacteriophage D'HERELLE sees the former—a view with which his critics may well disagree. As regards the power of adaptation there is general agreement that the substance is of a plastic nature and its virulence for bacteria can be augmented or altered; it shows also a definite adaptability towards other changes of external conditions. Prof. PRAUSNITZ, who after careful consideration adopts D'HERELLE'S view of a living organism, concludes, from the experiments detailed in the lecture published elsewhere in this issue, that the dimensions of the bacteriophage particles are in the vicinity of 20 $\mu\mu$; this is about a seventh of the size of the smallest known pathogenic microbe, that of bovine pleuro-pneumonia, and one-fiftieth of the diameter of the staphylococcus. In this estimate of size Prof. PRAUSNITZ is in close agreement with the conclusions independently arrived at by V. ANGERER by an optical method. He speculates whether so minute a body can carry out the complex functions of life. The dimensions given are well above those which theoretical calculations have shown to be the smallest at which life can be conceived to exist, and the experiments recorded upon the properties of the bacteriophage prove it to conform to the criteria which PRAUSNITZ sets up. One of these is the occurrence of random variability in the activity of the so-called organism, whilst the other is its adaptability to environmental alterations, a fact upon which D'HERELLE has likewise greatly insisted. Here the matter stands for the present. It is difficult to admit that such a phenomenon may be due to a living virus since it introduces a new conception. We have long been accustomed, quite irrationally, to regard bacteria as the smallest of living bodies limiting our purview to the accidental powers of the immersion lens and to shut out of our minds the possible existence of still smaller bodies leading individual or parasitic lives. Whatever the nature of the bacteriophage may ultimately prove to be, the phenomenon shows that large molecular groups upon the borderline of what we call life may possess some whilst lacking other of its attributes which we find so difficult to define.

The other and more immediately practical side of the problem is what functions, and especially what useful functions from man's point of view, the agent or organism may perform. D'HERELLE considers it utilisable in the treatment of bacterial infections and an important, if not the most important, factor in the rise and fall of epidemics. For him the decline of an infection, or the cessation of an epidemic, is in many cases due to the appearance of a bacteriophage active for the organism in question, which in a short space of time produces so great a mortality amongst these as to reduce them to impotence. He makes large claims for the termination of epizoötics by the introduction of a suitable bacteriophage amongst herds and flocks and for the treatment and cure of many types of human infections, more particularly of the intestinal ones, by such means. Here the outside confirmation of his results is exceedingly scanty and even in the favoured conditions of the test-tube the bacteriophage does not seem able to effect a *therapia sterilisans magna*. There are many other points in connexion with this fascinating subject upon which it is impossible to touch, such as the well-known decrease of bacteria in stored waters, the changes which occur in sewage, and the possible influence of so destructive an agent in ordinary bacteriological examinations. The many problems of this nature which await solution are intimately bound up with that of the essential nature of the bacteriophage, and here again the importance of pursuing what is sometimes rather depreciatingly called "academic research" becomes manifest.

STIMULANTS OF THE UTERUS.

WITH the end of August, 1927, comes the legal enforcement of a uniform strength for all preparations of pituitary extract sold in this country, an international conference, which met two years ago in Geneva under the presidency of Dr. H. H. DALE, having made arrangements for a common standard of reference to be adopted by all countries. The strength of the preparation is to be stated in units, the unit being defined as the amount of activity present in 0·5 mg. of the standard. The preparations on the market for the most part contain 10 units per c.cm.; if a

dose of 2 units is required the doctor must measure 0·2 c.cm. or 3·5 minims of the standardised solution. Now that uniform potency has been established by biological tests on uterine muscle, it remains to investigate and define the limits of safety in clinical dosage. This task has been attempted by the ideal combination for this purpose of an obstetric surgeon working with a pharmacologist. Mr. A. W. BOURNE and Dr. J. H. BURN have described in the summer number of the *Journal of Obstetrics and Gynæcology of the British Empire* (vol. 34, No. 2, p. 249) the results of joint investigations carried out at Queen Charlotte's Hospital. In order to obtain records of uterine pressure a rubber bag in the form of a hollow disc 1⅝in. in diameter was introduced into the human uterus. The bag was stiffened just sufficiently to prevent it from folding over while being inserted into the uterus by a stout iron wire bent into a ring, and the end of this wire was passed through a gum elastic catheter which was attached to the bag. A piece of rubber pressure tubing 12 feet long joined the other end of the catheter to a recording manometer. By means of glass T pieces inserted in the course of the pressure tubing, and connected with a water reservoir and with hand bellows, the air in the bag could be displaced by water. It was found that this bag could be inserted into the uterus of the unæsthetised patient, between the edge of the os and the membranes of vertex, and gently pushed up along the postero-lateral wall without producing any ill-effects. The results of several observations on 13 women including 11 primiparæ were that in the majority of women in labour a dose of 2 units of pituitary extract is sufficient to produce a definite and sometimes a striking increase in the strength and frequency of the uterine contractions. The effect produced by the injection appears to be of two kinds. In five cases the uterus passed into a mild tonic contraction with superimposed waves of rhythmic contraction. In eight cases, including the multiparæ, there was an increase only in the force and frequency of the uterine contraction, the intermediate relaxation being complete. The records show that it was in cases where the os was not dilated more than enough to admit two fingers that the injection most often produced tonic contraction and that in these, with one exception, it did not produce rapid increase of dilatation; in fact, they provide evidence that the least advantage is obtained when the injection is made too early in the first stage. The observers conclude that where labour is prolonged owing to sluggish pains a dose of 2 units should be of value, provided that, in primiparæ, dilatation is nearing completion. The effect of repeated injections was not studied, but the progress of one case observed indicates that the repetition of injections more than once an hour is not likely to be of any value. As to the dangers of pituitary extract, Mr. BOURNE and his collaborator express conviction that these are due solely to excessive dosage. In their experience a dose of 2 units is safe in any stage of labour in all cases where there is no mechanical obstruction. It was possible to study the effect of administration of pituitary extract after delivery of the placenta in two patients. The uterus was already acting well in both cases and the action of large doses (4 to 10 units) was surprisingly small, but the effect on a flabby or atonic uterus might be much greater.

Practitioners will welcome this quantitative study of results based on graphical records, for where so many factors are concerned as in the estimate of the effect of a uterine stimulant the value of clinical impressions is not easy to assess. As regards pituitary extract pharmacologists and clinicians are at least agreed that the preparations in general use are potent. Not even this measure of agreement is to be found in reference to an older drug, ergot, which many generations of doctors have held to be a most valuable uterine stimulant. The effect on the uterus of the different physiologically active substances to be found in ergot has also been the subject of inquiry by Mr. BOURNE and Dr. BURN, and this part of their work is of especial interest in view of the conflicting evidence on the subject. Attention was called to the urgent need for correlation of pharmacological and clinical findings as to the active principle in ergot as long ago as 1922, at a joint meeting of those sections of the Royal Society of Medicine specially concerned.[1] At this meeting the value of ergot in obstetrical and gynæcological practice was discussed with special reference to its present position in the British Pharmacopœia. Briefly, the situation is as follows. In accordance with an international agreement as to the method of preparing liquid extracts, the popular official liquid extract of ergot has since the 1914 issue of the B.P. been a watery, whereas it was formerly an alcoholic extract. The extract as now prepared contains little or none of the specific alkaloid, ergotoxin. America has disregarded the agreement and retains the alcoholic extract. This difference of technique is of considerable importance in assessing results, since, whereas the preparation of ergot commonly used in America is one in which the specific alkaloid is retained, British practitioners favour an extract from which the specific alkaloid has been removed in the process of extraction. This anomaly has led to the suggestion that the clinical activity of ergot is due not to the specific alkaloid, but to the presence of the putrefactive bases tyramine and histamine. Some precise method of testing clinical impressions of the efficacy of the various constituents of ergot in stimulating uterine muscle was thus urgently required. Mr. BOURNE'S optimism, expressed at the meeting already referred to, that some useful results might be obtained from an instrumental method of gauging uterine contractions has been justified. Though he and his collaborator have been able to study with the recording apparatus only a small number of cases, their general conclusions have been confirmed by a controlled investigation of clinical reports on normal women in the puerperal state some of whom have been given ergot in different forms.

The results show that neither histamine nor tyramine in the proportions present in the B.P. liquid extract is responsible for the traditional value of ergot, though histamine in large doses (2 mg.) has a relatively powerful effect on uterine muscle. Ergotoxin has a definite effect, not like pituitary extract in intensifying the process already in being, but in the production of a condition of uterine spasm which, though dangerous so long as the child or the placenta remain in the uterus, is admirably suited to the needs of the puerperium. Ergotoxin does not act rapidly, but only in 20 to 30 minutes after hypodermic injection. It is therefore suggested by these observers that a mixture of the two drugs in the proportion of 2 mg. of histamine to 0·5 to 1·0 mg. of ergotoxin might be the ideal agent for the control of post-partum hæmorrhage. The final conclusion reached is that, unlike the official fluid extract of ergot of the U.S.A., the extractum ergotæ liquidum B.P. is a wholly inert preparation and that the pharmacopœial method of preparing the extract should be revised in order that the specific alkaloid shall be present in the extract.

Annotations.

"Ne quid nimis."

CONTROL OF MOSQUITOES IN ENGLAND.

THE annoyance caused by the bites of mosquitoes is an aspect of their activities that has not received much medical notice. It is, however, a considerable nuisance in many parts of the country, and a few years ago it became so intolerable in Hayling Island that a campaign against the insects was started in 1920. Mr. F. W. Edwards, of the Natural History Museum, held that in prevailing conditions the brackish-water-breeding mosquitoes *Aedes* (*Ochlerotatus*) *caspius* or *A. detritus* was most probably to blame. The catching and identification of some thousands of the many millions of imagines, which packed every conceivable particle of cover, showed that the latter mosquito was almost solely implicated. The breeding-places, found nowhere in the residential parts, were finally traced, in 1921, to two saline marshes produced by seepage through the sea wall at high tide, and each situated about a mile and a half from the centre of the heavily infested residential district. Clearly, from the density of the insects, this considerable distance was well within the range of flight, affording a marked contrast to the habitual range of the malaria-carrying anopheles. On connecting marsh pools by ditches and emptying the whole system into the sea through sluice gates at low tide Hayling Island was rid of its nuisance.

It all seems delightfully simple, yet the result has actually been due to controlled and intensive research. This has included the collection and identification of thousands of imagines; the lengthy and at first fruitless search for their breeding-grounds; the identification of larvæ in the saline marshes; the determination of the degree of salinity of water in which they will breed (which was found to be as great as that of sea-water) and its hydrogen-ion concentration; the evaluation of larvicides—the usual suffocative petroleum film having been discarded for "a certain sanitary fluid containing 20 per cent. of soluble cresol," which kills in a strength of 1 in 28,000; the regular inspection of "water-places," a conveniently coined synonym for "potential breeding-places"; and, indeed, the collection of every possible scientific detail. All this was made feasible by the institution of the Hayling Mosquito Control with Mr. J. F. Marshall as honorary director and Sir Richard Gregory as chairman. Publicity and education were widely and wisely used. Hostility to the scheme was of course evident enough, and those who showed it had the satisfaction of the last word; for before it was started they pointed out that it could not succeed, and when it succeeded they said that it had been unnecessary.

By the end of 1924 the multifarious work of demonstration and research necessitated larger and more suitable premises, which Mr. Marshall erected at his own expense in the hope that the organisation would be placed on a permanent basis. Through the offices of Sir Richard Gregory, responsibility for the British Mosquito Control Institute was undertaken by a strong council, and about two years ago the building was opened by Sir Ronald Ross. A usefully illustrated report has now been issued covering the whole period. The Institute comprises a demonstration museum, a laboratory with apparatus ingeniously designed to fulfil its peculiar requirements, a photographic room including a specially lighted camera which for the first time reproduces with equal distinctness on the same plate the body-markings and the wing venation of mosquitoes, a library, administrative rooms, and other accommodation for such workers as avail themselves of the valuable opportunities which are here at hand. The scope of the Institute's activities has been widened to include experimental, educational, and research work in connexion with mosquitoes and other noxious insects particularly with a view to control. The directors aim at opening branches in other parts of the country, and wish to collect enough subscribing members to enable the Institute to carry on the work efficiently and to enlarge its usefulness.

THE RELATION OF TRAUMA TO THE LEUKÆMIAS.

TRAUMA is often cited as a factor in the production of hæmopathics. Their alleged causal relation often has to be considered in cases of compensation, and here the problem may be especially difficult, as in the life of most workmen it is easy to discover some history of injury preceding the illness more or less remotely. A case in the Roman law courts, in which a stoker was awarded damages for acute myeloid leukæmia on the ground that it was caused by a small burn of the second degree on the thigh, has led Prof. Salvatore Diez, of the University of Rome, to investigate the whole subject, and the results he has published [1] are interesting from a medico-legal point of view. He has examined all the reported cases, and offers some general considerations on the theoretical possibility that injury may affect the production, development, or course of the leukæmic syndromes.

Leukæmia is undoubtedly a disease of general distribution, not localised in this or that organ, nor apparently originating at any definite point in the hæmopoietic system; it involves the system as a whole, and the cause is presumably one that has a general action. It is difficult to imagine an injury having such an action; even serious damage to the spleen has not been found—except in a few doubtful cases—to give rise to leukæmia; and although both leukæmia and injuries to the skeleton and bone marrow are commonly reported, there is no sufficient evidence of a connexion between them. Thus from probabilities as well as from clinical observations it seems that only when a traumatic lesion is followed by a grave septicæmic process can any relation be maintained between the two conditions in a medico-legal sense. Even if it is admitted that trauma exercises an influence by diminishing the resistance of the organism, its action cannot be regarded as different from that of other agents which render the morbid cause more active and emphasise its effects. The question arises whether such intervention is required for development of the disease. Prof. Diez thinks that it is not. There are already, he says, in the organism the conditions necessary and sufficient to determine the morbid state; the trauma is merely a revealing element—one of those factors which call attention to it. Sooner or later the disease would manifest itself in any case, and the trauma, when the disease is already present, cannot be construed as an aggravation, since in industrial disputes this term implies a violent cause producing substantial modifications in the evolution of the disease such as could not otherwise be verified.

Would it not be right to speak of the relation between trauma and leukæmia as a coincidence? Prof. Diez has collected 30 cases of this supposed connexion, and has divided them into six groups: (1) Eleven cases in which the diagnosis seems erroneous or uncertain, where the data indispensable for sustaining the theory of a relationship are wanting, and which cannot therefore be taken into serious consideration; (2) two in which the long interval between the injury and the first manifestations of leukæmia exclude any relationship; (3) ten in which the very short interval between the trauma and death, or the manifestation, immediately after the injury, of a well-marked form of leukæmia, undoubtedly point to its pre-existence; (4) one in which causes other than trauma may have had an influence over the development of the leukæmia; and (5) six in which it would be hazardous to draw any conclusions for medico-legal purposes, as there was no proof that the disease was not present before the injury. Even slight experience of leukæmic

[1] Policlinico, Medical Section, August 1st, 1927.

affections brings a knowledge of the profound changes that may be present in the blood without functional disturbance, and rapid and progressive development of the disease does not in the least exclude pre-existence of the morbid process. Between the chronic cases and those which are apparently acute from the commencement are those—not very rare—in which the disease, after existing for a time without appreciably affecting health, suddenly begins to run a rapid course, with more or less rise of temperature and progressive deterioration in the general condition. The sudden change is probably due to diffusion or extension of the morbid process to important sections of hæmopoietic tissue, and the recognition of such forms has induced some observers to maintain that there is no ætiological difference between the very acute and the chronic leukæmias. In determining the possibility of a traumatic factor in the ætiology, it is necessary to be able to exclude other factors which can determine the development of the disease. This is difficult, as we are ignorant of what they may be. In the meantime, Prof. Diez considers that the reported cases offer no proof that leukæmia can originate from trauma.

KEY INDUSTRIES: THE CASE OF SPECTACLES.

UNDER the provisions of Section 1, Subsection (5), of the Safeguarding of Industries Act, 1921, and of Section 10, Subsection (4), of the Finance Act, 1926, complaints as to the improper inclusion of articles in, or their exclusion from, the lists of articles chargeable with duty under Part I. of the Safeguarding of Industries Act, as amended by the Finance Act, 1926, have to be referred for decision to a tribunal consisting of the referee appointed by the Lord Chancellor and of two persons selected by the Lord Chancellor from a panel of persons of special scientific attainments appointed by the President of the Board of Trade. The Lord Chancellor has appointed Mr. W. A. Hudson, K.C., to be the referee, and the President of the Board of Trade has appointed the following gentlemen to be the panel of persons of special scientific attainments: Mr. A. Chaston Chapman, F.R.S., Prof. F. G. Donnan, C.B.E., F.R.S., Dr. J. H. Jeans, F.R.S., Prof. F. A. Lindemann, F.R.S., Prof. S. Smiles, O.B.E., F.R.S., and Prof. J. F. Thorpe, C.B.E., F.R.S. The Board of Trade announce that they have received a complaint that spectacles, eyeglasses, and monocles have been improperly excluded from the lists of articles chargeable with duty under the Safeguarding Act as amended. The complaint will be referred for arbitration to a tribunal consisting of the referee, Dr. Jeans, and Prof. Lindemann, and any communications regarding this complaint should be addressed without delay to the Principal Assistant Secretary, Industries and Manufactures Department, Board of Trade, Great George-street, London, S.W. 1.

THALLIUM EPILATION FOR RINGWORM OF THE SCALP.

As a first step in the treatment of ringworm of the scalp it is desirable to remove all the infected hair. This may be done by exposure to X rays or by giving a single dose of thallium acetate, and for young children the second method has undoubted advantages. Thallium is a poison, and mild toxic symptoms often follow its administration. But although the drug has been widely used we are unaware of any case of fatal poisoning, and it seems likely that the treatment has come to stay. Obviously its use requires great care, as we pointed out [1] when the first results were published in this country by Dr. G. B. Dowling and Mr. J. Kelman.[2] The method was introduced in Ireland by Dr. Maurice Drummond,[3] and to the July number of the *Irish Journal of Medical Sciences* he contributes an article which should be useful to those who wish to try it for themselves. A paper by Dr. E. T. Freeman in the same journal is also worth perusal, whilst further comment will be found in the report of a discussion which we publish on p. 550. The chief conclusions which emerge are as follows: (1) the treatment appears to be safe when properly conducted; (2) it is very much cheaper and simpler than epilation by X rays; (3) the child need not be restrained and is never frightened; and (4) permanent alopecia does not occur. Though the technique is simple, the intending operator must faithfully observe the details of administration, which should never be left to a nurse or unqualified person. The contra-indications and the question of repetition of the dose require very careful consideration in every case, experiments at King's College Hospital[4] supporting Prof. A. Buschke's recommendation that a second dose should not be given within two or three months of the first. Administration by the mouth has hitherto been the rule, but Dr. H. C. Semon reports that hypodermic injection of the same quantities is equally effective.

HEALTH IN OUR FACTORIES IN 1926.

As read in figures of mortality and sickness caused by industrial accidents and diseases, the record for 1926, given in the annual report of the Chief Inspector,[5] is excellent; but its excellence has to be discounted by the extensive closing down of work during the year due to the coal stoppage. The tendency for the small workshop to give way to the larger factory has continued; as has also the tendency for industrial growth to be more rapid in the South-East of England than in the North and Midlands. Of particular industries the motor-car trade, sugar-beet factories, and tin-plate making were developing satisfactorily; but depression and short hours is the more usual story. The chapter dealing with accidents indicates the efforts being made to promote the adoption of safety-first methods; the results in every ease are unchallengeable and of great economic value. Yet the methods spread slowly. Close investigations of the ways in which accidents occur continue to be made, and, as ever, reveal the paramount importance of the personal as contrasted with the mechanical factor. The substitution in metal grinding of abrasive wheels for sandstones continues, reducing at once dangers from bursting stones and from the dust hazard. The granting of compensation to metal grinders with silicosis is expediting this beneficial revolution. The position of the young person in industry receives special consideration; vocational selection on engagement, although far from general, is increasing; young persons are employed for the same hours as adults, but the number employed in dangerous trades is comparatively small. Labour-aiding devices more and more save them from heavy work beyond their strength; but posture at work is seldom considered, either in adjusting the height of the machine to the youth or of the youth by adjustable seats to that of the machine. The sports side of welfare is doing good service. Better instruction on accident prevention to youths is needed. The encouragement of dancing in the dinner-hour caused girls on monotonous repetition processes to work much better. Vocational and general continued education is found to improve craftsmanship and output. Some account is given in the report of advances made in labour-saving appliances—a fundamental factor in reducing unskilled labour and raising the standard of industrial employment and wages; in this direction lies advance in racial improvement. The greater the saving of strenuous and arduous labour, the more efficient and economical is work, and the less the risk of accidents. Dr. J. C. Bridge, who has succeeded Sir T. M. Legge, writes on matters essentially medical. When dealing with lead poisoning he points out that so long as lead is used poisoning will occur; only by use of non-toxic materials can poisoning be eliminated; and the

[5] Annual Report of the Chief Inspector of Factories for the year 1926. H.M. Stationery Office. 1927. Cmd. 2903. Pp. 139.

enormous advantage gained from use in the potteries of low solubility or leadless glaze is quoted. Four cases of tumours in the bladder occurred among aniline workers; poisoning from this source is much more frequent in warm than in cold weather. Notified cases of epitheliomatous ulceration due to occupation continue to increase in number; there were 187 with 49 deaths in 1926 as compared with 45 with one death in 1920 when notification was first demanded; mule spinning, 88 cases with 20 deaths, was by far the largest contributing source. Dermatitis among bakers is ascribed to manipulating dough, which is hygroscopic and breaks down the protective horny layer of the epidermis; here, as in other industries, cleanliness and meticulous attention to the skin is the great protective barrier. Several interesting inquiries are recorded, of which the distinctive feature, as against inquiries of past times, is the absence of serious findings; undoubtedly conditions of work to-day are less risky and more civilised. The use of electricity, which means greater risk from shock, continues to increase; but that no increase occurs in electrical accidents is a praiseworthy testimony to expert and skilled forethought in supervision of appliances permitted to be used.

CONCERNING LUMBAR PUNCTURE.

THE discussion reported on page 553 reveals a certain amount of disagreement about the readiness with which lumbar puncture should be done, whether for diagnostic purposes or for estimating the effects of treatment. Of its value for both these purposes there can be no question, but from the patient's point of view the operation is at best unpleasant, and however skilfully performed, it is not altogether free from the risk of uncomfortable after-effects. It is true that fear of the unknown accounts for most of the patient's aversion, and those who have been frequently punctured become almost indifferent; but the after-effects may undoubtedly be very trying, and if lumbar puncture were applied indiscriminately the proportion of cases in which troublesome sequelæ occurred would be considerable. As long, however, as it is confined to cases of organic (or suspected organic) nervous disease, and reasonable precautions are taken, the percentage of patients who suffer any serious discomfort is small. Disseminated sclerosis seems to render subjects particularly liable to rather prolonged headache after the withdrawal of even a little fluid; cerebellar tumours and cerebral tumours in certain situations provide a not inconsiderable risk of death if lumbar puncture is performed otherwise than with the greatest care; but in most other organic nervous diseases —neurosyphilis, meningitis of all kinds, encephalitis, poliomyelitis, spinal tumours, and the like—lumbar puncture is well borne and often gives relief. Where there is no organic nervous disease and no pathological change in the cerebro-spinal fluid, unpleasant after-effects, such as severe headache, nausea, and vomiting, seem to occur rather more often, and in doubtful cases it should always be considered whether the advantages outweigh the possible disadvantages. Syphilitic infection so often affects the central nervous system that it is certainly of some importance to know when changes of a syphilitic nature are present in the cerebro-spinal fluid, though the knowledge gained can make little difference to treatment as long as the Wassermann reaction in the blood is positive. Examination of the cerebro-spinal fluid may be advisable, as Colonel L. W. Harrison points out, when there is difficulty in rendering the blood Wassermann negative, and before any syphilitic patient is discharged from treatment.

The cause and prevention of the untoward symptoms that sometimes follow lumbar puncture are discussed in the *Presse Médicale* of August 13th by Dr. J. Mouzon, who considers that they are due either to hypotension or hypertension of the cerebro-spinal fluid. Hypotension may be brought about and sustained by the escape of fluid into the subdural space and tissues through the puncture in the membranes made by the needle, whilst hypertension is attributable to irritation of the dura, which reflexly stimulates production of cerebro-spinal fluid. In hypotension the symptoms come on at once but are less prolonged; they are often accompanied by muscular weakness, tachycardia with low blood pressure, and oliguria; the effect of posture on the headache is marked. In hypertension the onset is slower and the symptoms last longer; posture has little effect on the headache, and there may be slight mental confusion, and tachycardia without low blood pressure. As means of preventing symptoms after puncture, the head should be kept low and the hips raised by a pillow. All muscular effort by the patient should be avoided during the puncture and for some hours afterwards. When the needle is felt to be through the dura, but the fluid does not flow at once, the needle should only be moved slowly and cautiously after a short interval, and should not be hurriedly withdrawn and inserted again. The fluid often comes slowly at first; it should never be withdrawn quickly, and no more should be taken than is necessary for diagnosis. The patient should lie in the lumbar puncture position for 20 minutes and then be rolled slowly over on to his back. After a few hours his head may be raised with pillows and food can be given, and in 24 hours he may get up. With these precautions, according to Dr. Mouzon, most of the unpleasant sequelæ are avoided.

If these theories of the causation of symptoms are correct, it is clear that the smaller the needle used the smaller will be the likelihood of leakage of fluid, the less the irritation of the dura, and the slower the delivery of the fluid. A fine needle, however, is not strong enough to pierce the skin and ligamentous structures before the dura is reached, at any rate without risk of breaking. This difficulty is overcome by the use of a needle within a needle, the inner one coming into action only after the ligamentum subflavum is pierced. Such needles, Dr. Mouzon says, have been described by Antoni[1] and W. Wechselmann,[2] and he considers that their use greatly minimises the chances of unpleasant symptoms following lumbar puncture, even when the patient is allowed to walk about immediately afterwards.

HIGHER QUALIFICATIONS FOR CANADIAN PRACTITIONERS.

A RECENT editorial article in the *Journal of the Canadian Medical Association*, dealing with the development in population and importance of the Dominion, points out that such advances carry with them the necessity to raise the standards in all special social activities. Problems which have been solved or have solved themselves in the countries of older civilisation present themselves regularly to newer States, and for some years the question of the development of medical education in Canada has been a subject of particular interest to the Association. Two years ago the Association made representations to the Royal College of Surgeons of England upon the desirability of facilitating for Canadian graduates the attainment of the Fellowship. The representations made were to the effect that, as the expenditure of time and money required by the journey to London to sit for the examinations had a very deterrent influence on Canadian candidates, it was hoped that the College would devise a method by which examinations could be held in Canada. It may be remembered that the justice of the arguments of the Association was recognised handsomely by the College, and in a report from the Nomination Committee of the College upon the Primary Examination for the Fellowship, the following recommendation was made and adopted by the Council in May last: "That it is desirable to send examiners to the Dominions to

[1] Antoni: Ugeskrift f. laeger, 1924, lxxxvi.
[2] W. Wechselmann: Med. Klin., Dec. 18th, 1924 p. 1787.

conduct a Primary Examination for the Fellowship, of the same standard as the examination in this country, on conditions to be hereafter determined, provided that satisfactory arrangements can be made." The journal of the Association announces that in all likelihood this Primary Examination in anatomy and physiology will be open to Canadian undergraduates who have completed advanced courses in the subjects, as well as to qualified graduates, and it is hoped that the first examination may be held in Canada next summer. In the meantime Mr. S. F. Cowell, the secretary of the College, and Mr. F. G. Hallett, the director of examinations of the Conjoint Board, are conducting the necessary negotiations with the Canadian authorities.

QUARTERLY CUMULATIVE INDEX MEDICUS.

THE product of the fusion of the two most trustworthy journals of reference to medical and allied publications in the English, if not in any language, has taken an agreeable form. The first issue of the Quarterly Cumulative Index Medicus,[1] which has just reached us, is a handsome volume, light in weight, firmly bound and clearly printed. It contains for the period under review the names of the writers and the titles of the subject matter, indexed alphabetically, of all the contributions to all the general and special medical journals received in the library of the Surgeon-General's Office in Washington, and these include practically the whole medical literature of the world. In a valedictory foreword to the last (supplementary) number to be issued of the Index Medicus, the editors gave a brief history of the evolution of this work, which dates from 1879, whereas in the *Journal of the American Medical Association* of July 2nd the genesis of the younger parent, the Quarterly Cumulative Index of the American Medical Association (started in 1916), is set out. Those who habitually use either publication are well aware of their peculiar advantages; those who are familiar with neither may note that the last-named index of contributions to the more important periodicals was on the whole more convenient for current use, whereas the Index Medicus was more exhaustive. The duplication of labour and expense was recognised to be unnecessary and wasteful, and last year the new Quarterly Cumulative Index Medicus was carefully designed to combine the best features of the classification of both works. The index is alphabetical as to authors and subjects. The author's titles are now given in full in the original languages, with the exception of titles in the Slavic, Scandinavian, and Oriental languages, which are presented in English translation; the subject entries are brief English abstracts of the actual content of the articles in question, without references to the titles, unless the latter happen to be accurately descriptive. Cross-references are frequent. The new books published throughout the world during the half year are presented, for ready reference, both by authors and by subjects and with prices attached at the beginning of the volume. Incidentally these are less numerous than might have been expected—for example, only ten works appear to have been published on surgery, six of which are in the German language. It is not quite clear what practice is followed when a new edition is entirely re-written by living workers of a well-known classic, the original name being retained. An alphabetical list of publishers of the books and periodicals indexed (American and foreign) and an alphabetical list of all the periodicals indexed are also included. The number of current periodicals now coming into the Surgeon-General's library is about 1925. They include all important periodicals of anthropology, biology, psychology, and even those of chemistry, physics, and general science, which may publish articles bearing on medicine. Any unusual and noteworthy books or articles of this character not apt to be represented in regular medical channels will be included if sent to the Chicago Editor (American Medical Association). Immense labour is involved in the preparation of such an accurate and complete account of the world literature of our science. The American Medical Association and the Carnegie Institute, which bears a portion of the expense of publication, deserve the gratitude of medical workers in all countries.

PROTECTION AGAINST MEASLES.

NOT long ago Dr. J. E. McCartney reviewed in our columns [1] certain recent work on measles and referred to a green-producing diplococcus isolated by Ruth Tunnicliff and thought to be of ætiological significance in the disease. An antiserum made by injecting this organism into goats is said to protect children against infection, and Tunnicliff and White [2] now report similar results obtained with the serum of an immunised horse. Carbolised broth cultures of the diplococcus were injected into the animal at intervals of from three to seven days, and when a basal immunity had been obtained it was inoculated with living diplococci by the Dochez method. Further injections of killed whole broth culture and living organisms were made alternately. The serum from the several bleedings of the animal was pooled; part was concentrated by a modified Banzhaf ammonium sulphate method and the rest was used unrefined. The serum was found to contain opsonins and neutralised the diplococcus antigen used for cutaneous tests on rabbits and on human beings; it also protected mice against fatal doses of green-producing measles diplococcus. The effect on human beings has not yet been studied on a large scale. The unrefined serum, administered in doses of 5 c.cm. to five children on the fourth day after exposure to measles, protected one child, modified the disease in another, and apparently had no effect on the other three. In another series 10 c.cm. was given to each of four children on the fourth day after exposure, and one child developed unmodified measles. Of the concentrated serum 10 c.cm. was given to each of four children exposed to measles four days previously. Of these two escaped, one had mild measles 14 days after exposure, and the other contracted mild measles 30 days afterwards. These cases are too few in number for any conclusions to be drawn further than that the serum seems to give protection in some cases but not in others.

MEDICAL CANDIDATES FOR THE DAIL.

THE general election of the new Dail is to be held on Sept. 15th, and of the 260 candidates for 150 seats, 11 are medical men. Of these, Sir James Craig, one of the sitting members for Dublin University, has, with his colleagues, been returned unopposed. He sits as an Independent supporter of the Government. Of the remaining ten five are Government candidates and five are Fianna Fail. Mr. T. Hennessy, who was elected at a by-election only a fortnight ago, has again to contest his seat without having entered the Dail. His return for South Dublin City is, however, almost certain. Dr. Myles Keogh, another of the candidates for the same division, has hitherto sat as an Independent, but now comes forward as a Government candidate.

Sir Arthur Keith was able to announce on Tuesday last to the British Association that, in answer to his appeal to the public for the preservation of Downe House, the home of Darwin, he had received a telegram from Mr. Buckston Browne making himself wholly responsible for the national gift. No other contributions will be necessary. Mr. Buckston Browne's offer, which was gratefully accepted by the Association at the closing of its sessions, implies a gift to the nation amounting, with a certain endowment, probably to as much as £14,000 or £15,000; he has made the valuable suggestion that the office of curator of the premises should be given to a suitable medical man.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXL.—THE TREATMENT OF G.P.I. (PARESIS; DEMENTIA PARALYTICA).

II. THE CHRONIC CASE.[1]

SOME cases of paresis which are not responsive to treatment, in spite of early diagnosis and the prompt application of the methods were outlined last week. Some patients continue to deteriorate slowly; others improve, but psychical defect remains, and they are not able to look after themselves or resume their work. There has also to be considered the patient who, by reason of some physical defect or age, is not suitable for the use of malarial therapy. Some of the slowly dementing forms of paresis present great difficulties to the practitioner. The patient has no insight into his condition, may show profound loss of memory, may have attacks of mild confusion, may be erratic and even dirty in his habits, and yet does not become so disordered in his conduct or speech as to justify a certificate of unsoundness of mind under the Lunacy Act. Yet for the majority of chronic cases certification and treatment as an in-patient in a mental hospital becomes necessary sooner or later. Nursing a chronic case at home or in a suitable nursing home involves considerable expense, since adequate assistance must be available. It can be done, and sometimes there is no alternative.

Treatment should ensure as much fresh air as is possible. The patient must always be accompanied when walking or driving. An effort should be made to provide some simple out-door amusement to interest him, for he will often pass many hours playing at some easy game. Bowls, clock golf, skittles, are among the games which are easily set out on the smallest patch of grass. In the later stages of enfeeblement care must be taken to see that the patient is not unduly exposed to the weather, especially when the wind is easterly. Patients become very liable to attacks of broncho-pneumonia as the disease progresses, and a fatal illness not infrequently follows a walk or drive in a cold east wind.

Diet.

The diet should be liberal, though care must be exercised to see that any tendency to gross over-feeding is checked. Practically all solid food must be minced; paretics choke themselves easily with meat, or with potatoes, which they often swallow whole. The supply of meat should be sparing, and it should be arranged that the chief meal be taken at midday. Bones must be removed from fish; eggs and milk should be given freely, and will form the greater part of the dietary in the later stages. The absolute avoidance of alcohol is a fetish. Indeed, many patients are better for 1½ to 2 ounces of whisky or brandy taken with the principal meal. All wines should be forbidden. Tobacco in moderation may be allowed.

Sleep.

Insomnia is rarely a feature of the chronic case of paresis. In practice it will be found that somnolence is much more usual. For this reason patients should be put to bed early; 8 or 9 P.M. is not too soon, and the patients often sleep the night through. The bedroom should contain very little furniture; linoleum is the best covering for the floor. A patient who is confused is safer on a box or spring mattress placed on the floor of the room. He may be even safer on a single mattress on the floor. The discomfort of this couch may be mitigated by placing under it a cork mattress, such as is sold in camp outfits.

Insomnia and restlessness at night may be relieved by a dose of castor oil. If this measure is not successful sleep can generally be secured by ordering 5 gr. each of the three bromides, 6 gr. of medinal, or 1 or 2 drachms of paraldehyde or amylene hydrate taken on retiring. The bowels must be kept functioning rather freely. Patients require larger doses of laxatives than the normal person. Castor oil should be given when there are attacks of irritability, restlessness, mild confusion, or excitement. An inspection and palpation of the abdomen should be made frequently by the physician in charge, with a view to detecting a distended bladder. A paretic in the advanced stages, or even before, will walk about without complaint with a very distended bladder. Retention, or distension without actual retention, is relieved by the use of a catheter, seldom necessary for more than one or two days.

Seizures.

If the management of a paretic be successful, fits will be rare or unknown. If they occur, they may be epileptiform or apoplectiform in type, or resemble a Jacksonian attack in which there is no loss of consciousness. The epileptiform attacks are best treated with an injection of a morphine salt. If the fits continue lumbar puncture sometimes relieves them instantly. Chloroform anæsthesia may be necessary in a severe case. A sedative mixture containing 10 gr. of potassium bromide and 5 gr. of chloral hydrate may be given for a few days after a seizure. A mixture which is useful in preventing seizures contains 15 gr. of hexamine and a similar quantity of acid sodium phosphate. Whatever its action, the regular use of hexamine will produce satisfactory results in limiting the "fits" of paresis. The paralyses following the fits clear up rapidly, often within a few hours. It is probable that antisyphilitic treatment also minimises the risk of fits. Novarsenobillon, and mercury and iodides have some influence, though there are some patients who do not tolerate either very well, and in this case the drugs should then be discontinued.

During the confusion and paralysis following a seizure it may be necessary to feed the patient artificially. Swallowing becomes difficult or temporarily impossible, and attempts at spoon-feeding are dangerous. It is better to use a nasal tube once or twice a day so that food and necessary medicines can be given with safety and certainty. The bowels may prove difficult to move after a fit; an enema should be used, a simple soap solution being all that is required.

Sudden attacks of vomiting of the cerebral type may herald a seizure, or may be a troublesome feature of the disease. The diet should be cut down to liquids, hexamine prescribed, and a brisk purge ordered.

Late Stages.

As the disease progresses wasting becomes pronounced, and there will be increasing feebleness and inability to walk or stand. At this period there will also be a rarefying osteitis of the long bones and ribs, and a fall or other slight injury is very liable to produce a fracture. Friends should be warned of this serious possibility. Pronounced ataxy and feebleness is best dealt with by putting the patient to bed, preferably on a water- or air-bed. Improvement often follows, and in a week or two the patient can be got up again. Wasting becomes pronounced, and great efforts will be needed to prevent bed-sores. Measures must be taken to keep the patient clean and dry. Constant inspections are necessary to see if changing is required. While the patient is still up a large sanitary towel is useful to prevent the soiling of clothes. It may be used when the patient becomes bed-ridden, but care must be exercised to see that the towel is changed at once when wet or dirty. Wet sheets and garments must be removed at once, and when in bed the patient's position should be altered hourly, both by day and night. A night nurse is a necessity in the later stages. A careful toilet of the skin must be carried out twice daily, and prominent points rubbed with spirit and dusted with an antiseptic powder. Should bed-sores appear they may be treated with any mild antiseptic dressing, which must be renewed frequently. A

[1] Part I., on the Recent Case, appeared last week.

sluggish bed-sore will often heal after it has been fomented for a few days. In the final scenes artificial feeding may be required, and is easily performed through a nasal tube.

Antisyphilitic Treatment.

Many patients seem to derive benefit from regular courses of N.A.B. or sulfarsenol, the latter drug being given intramuscularly. A course may be given at intervals of 4–6 months. The dosage should be small to commence with and increase gradually. Commencing with 0·45 g. of N.A.B. or 0·18 g. of sulfarsenol, the dose is increased to 0·9 g. and 0·60 g. respectively at a slow rate, the intervals between the injections being a week, and six or eight injections complete the course. Improvement in general health may result, but the use of these preparations is inadvisable when the patient does not tolerate them well, or if there is no definite physical improvement.

The same remarks apply to mercurial preparations. A mixture containing 5 gr. of potass. iodid. and a drachm of liq. hydrarg. perchlor. t.d.s. may be helpful, and relieves headache, if present. A pill containing ¼ gr. of hydrargyri iodid. virid. is another good prescription, and is given twice daily, with regular rests. Should mercury in some form produce improvement, and be well tolerated, it can be safely continued. If there is no physical benefit, or any sign of intolerance, continued use of the preparations of either arsenic or mercury are not justified.

Conclusion.

The practitioner should not fail to warn the family of a paretic of the risks attached to nursing at home. There may be attacks of excitement, or sudden impulsive actions on the part of the patient which almost invariably indicate legal care to be a necessity. In a small establishment home care is a grave problem, and if the mental condition permits of certification, the patient is just as contented in a mental hospital. The care of property is a question which need present little difficulty. This can be dealt with by procedure under Section 116, Subsection (*d*) of the Lunacy Act, by which the property of the patient can be cared for, provided he be shown to be incapable of managing his own affairs by reason of mental infirmity arising from the disease.

Physician for Mental Diseases to St. Mary's Hospital, Paddington.

Special Articles.

THE DEATHS OF MERCHANT SEAMEN IN 1925.

BY FLEET-SURGEON W. E. HOME, M.D.

THE Board of Trade's "Return of Shipping Casualties to and Deaths on Vessels Registered in the United Kingdom" (excluding the Irish Free State) for 1925, the only vital statistic for the merchant marine, was issued in April. It has the same eight pages as before, but costs 2*s.* only, instead of 3*s.*, which is a slight improvement to begin with. The number of seamen concerned is much the same as in the year preceding, being for "first crews of ships," in steam, British, 168,208; foreigners, 11,864; and Lascars, 54,969; total for steam, 235,041; and in sail, 1983, who, as nothing is said to the contrary, may all be taken as British. No hint is given as to the average numbers employed daily, but the figures of previous five-yearly censuses of seamen suggest that the average is generally 90 per cent. of the "first crews"[1]; and we therefore adopt, as the numbers probably employed daily (the figures with which to attempt calculating death-rates), British, 153,131; foreign, 10,678; Lascars, 49,472; and hope they will give us a tolerable approximation. Then we have, per 1000, the following as the likely death-rates:—

—	In sail.	In all.		
		British.	Foreign.	Lascar.
Death-rate for disease ..	2	2·05	4·97	5·33
„ „ alcohol ..	—	0·22	0·46	—
„ „ accident ..	12	3·25	3·74	1·74
—	14	5·52	9·17	7·07

Sailing ships (1983 men, 28 deaths) show a lesser death-rate than steamships by disease, but a vastly greater loss (treble) by accidents. They have less and less influence on the total from year to year, as the numbers they employ (in 1905, 25,000; now, 1983) are constantly decreasing. Even with so few in sail British merchant seamen have a risk of death by accident, 3·25 in 1925, nearly three times that (1·13) stated for the coal-miner, underground, on p. 191 of the recent report of the Royal Commission on the Coal Industry. That Commission stated the rate in shipping, 1922–24, as 1·28, but did not give the exact reference; in those years the death-rate from accidents of seamen on their ships was 3·15, 2·78, and 2·60. In 1925, as we have seen, it was 3·25; cases influenced by alcohol are all and always excluded.

Since the last return, which appeared rather more than a year ago, the Board of Trade has taken counsel with experts from the offices of the Registrars-General of England and Wales, and of Scotland, and with other authorities, and has adopted some at least of their advice, so that the list of the diseases which were the causes of the deaths of seamen no longer causes a shock of pained surprise to the doctor who chances to read it, tuberculosis being no longer distinctly separated from the diseases due to infection. Yet the list is not quite what is wanted. There is only room on it for 27 lines of diseases or groups of diseases mentioned. Now we all know that if people were asked to submit the best 27 headings under which to group to best advantage, most instructively, the deaths which from year to year might occur among seamen, no two would submit lists that were identical, yet undoubtedly certain of the more frequently recurring and more important diseases of seamen would be included in all such lists if submitted by doctors who were acquainted with the prevalences of disease and death among seamen. Cholera, dysentery, plague, yellow fever, malaria, beri-beri—diseases to which seamen are by their occupation more exposed than other men—would probably appear in all, and pneumonia, enteric fever, and small-pox also, causes of too frequent deaths and to be prevented. Yet plague, dysentery, yellow fever, and beri-beri are not given lines on the form itself (though they are wisely mentioned in the notes), while valuable lines are surrendered to various diseases of children, rarely attacking seamen, measles, whooping-cough, scarlet fever. Whooping-cough! Just think of it! In 1922 (that book happens to be at hand) there were 2864 male deaths from whooping-cough in England and Wales; most of them occurred under the age of 5 years; only *two* happened among men of the age of seamen (15–60), yet one valuable line in the return is wasted on this disease, which a seamen will only get by an accident (the Navy does not give whooping-cough one of its 100 lines of diseases), while plague, of great importance to the seamen, is crowded out, like beri-beri, from which there were

[1] Proc. Roy. Soc. Med., 1926, xix., Epidemiology, p. 97.

21 deaths. Naturally, there is no doctor's signature expressing approval with this list of diseases, only the same layman's as last year. Very likely he will learn better in time, and he has done better this year.

There were, in 1925, 843 deaths among British seamen from disease, the most important single cause being pneumonia, 49 (46 in the previous year); there were fewer deaths from enteric fever, 12 (29); from malaria, 11 (28); from tuberculosis of the lung, 11 (21); and from other tuberculosis, 3 (12). There were more from alcohol, direct and indirect, 34 (26), and more from accidents, 496 (433); the numbers for the various accidents were: heatstroke, 20 (9); murdered, 8 (4); suicide, 37 (28); lost in accidents to ships, 186 (132); lost in accidents on board, 150 (178); in accidents ashore, 95 (82). Lascars had, as usual, a higher death-rate for disease than had British seamen, but a lower rate for accidents. Their rates were increased for pneumonia, 51 (49) cases; for phthisis, 48 (43); and for beri-beri, 20 (11). Anyone in the profession can see there should be an inquiry about these 20 deaths from beri-beri, with a view to future prevention, but we do not hear of such inquiries. How long will it be before the profession insists there shall be a special medical officer, of the standing of a medical officer of health, appointed to see that the necessary thought is given to the health of merchant seamen?

It appears as if seamen in 1925 had a death-rate from enteric fever four times that of the standard for males of their ages in England and Wales, for small-pox 100 times, for accidents six times, but only half the standard for pneumonia, and a twentieth of that for tuberculosis of the lung. The phthisis-rate is less comparable for seamen than are others, for phthisis is a chronic disease, and the death-rate shown for seamen cannot be complete, as patients cannot go on serving, and so most of them drop out of the ranks of seamen before their deaths are registrable, so the Board of Trade does not hear of them and they are not counted in the return. The death-rates here stated for pneumonia are: for British seamen, 0·32; for Lascars, 1·03; for the Army in 1925 the rate was 0·33; and for the Navy in 1924 (last year available), 0·14.

One definite advance is notified this year; most of the deaths are, it is stated, now certified by a doctor, so their classification is more reliable. We are still left without any convincing statement of the average number of men employed daily, and we are without any officially-propounded death-rate, however approximate, for seamen in 1925. In addition, there is no discussion of the deaths that occurred, nor is there any suggestion that the prevention of any of these diseases or deaths is being actually considered; such prudent medical procedures could hardly have been expected from a body which has no permanent professional adviser, and is only intermittently professionally advised.

The Board of Trade seems slow in learning, for although it has during 30 or 40 years, perhaps longer, exercised supervision over seamen's diseases, it still thinks whooping-cough among the 26 more important of them. Was it not judicious of the Royal Sanitary Institute to forward to the Board of Trade and the Ministry of Health a resolution that the care of the health of the men of the Merchant Service should be given in charge to the Ministry of Health, the Board of Trade not being specially organised for that duty?

DEATHS AND DEATH-RATES FOR MERCHANT SEAMEN IN 1925.

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS IN 1927.

WE are requested by the Registrar of the General Medical Council to publish the following list of medical practitioners who have not replied to his inquiries as to the accuracy of their addresses. Anyone who finds his or her name included in this list should communicate immediately with the Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W. 1, otherwise the name will be omitted from the next issue of the Medical Register.

Abdurahman, Ismail, M.B., 1915(E).
Abushady, Ahmed Z., L.M.S.S.A., 1915(E)
Adams, Edward J., M.R.C.S., 1867(E).
Addinsell, John H., L.R.C.P., 1901(E).
Addison, Hallowes L., M.R.C.S., 1914(E).
Adeney, George C., M.R.C.S., 1903(E).
Ahearne, Joseph, L.R.C.S., 1871(E).
Ahmad, Abdul M., M.R.C.S., 1916(E).
Ahmed, Esawy, M.R.C.S., 1917(E).
Aiken, James P., M.B., 1912(I).
Ainley, Frederick S., M.B., 1893(S).
Ainsley, James E., L.R.C.P., 1916(E).
Ainsworth, Douglas R., M.R.C.S., 1922(E).
Alcorn, Robert M., L.R.C.P., 1914(I).
Alexander, Frederick H., M.B., 1921(E).
Allen, Norman, M.R.C.S., 1886(E).
Allman (Mrs.), Ethel A., M.B., 1909(E).
Allport, Evett G., M.R.C.S., 1902(E).
Alper, Minnie, M.B., 1922(E).
Anderson, Charles M., M.R.C.S., 1876(E).
Anderson, Florence M., M.B., 1922(I).
Anderson, Frederick, M.B., 1897(S).
Anderson, John C., M.B., 1897(E).
Anderson, Thomas Cochrane, M.B., 1882(S).
Andrew, George, M.R.C.S., 1874(E).
Andrew, Philip O., O.B.E., M.R.C.S., 1896(E).
Anthony, Christie M., M.R.C.S., 1915(E).
Arbuckle, Donald, M.B., 1911(S).
Areskoug (Mrs.), Carolina, L.S.A., 1904(E).
Armstrong, Harry, L.R.C.P., 1903(S).
Armstrong, Margaret M., M.B., 1924(I).
Armstrong, William L., M.B., 1898(I).
Arnold, Frank A., L.S.A., 1892(E).
Ash, Alfred E., M.R.C.S., 1890(E).
Ashburner, Robert, L.R.C.P., 1883(E).
Atkins, Francis T., L.S.A., 1873(E).
Austin (Mrs.), Cristina, M.B., 1905(S).
Avarne, Claude H. B., M.R.C.S., 1914(E).

Bailey, Edwin R., M.R.C.S., 1914(E).
Bainbridge, Philip G., L.R.C.P., 1923(S).
Baker, Leonard T., M.B., 1909(E).
Banerjee, Prabodh C., L.R.C.P., 1919(E).
Barff, George P., L.R.C.P., 1899(E).
Barker, John E., L.R.C.S., 1863(I).
Barrett, Joseph H. P. B., M.B., 1907(I).
Barry, David T., M.B., 1894(I).
Barry, John M., L.R.C.P., 1901(I).
Barry, Stephen J., L.R.C.P., 1910(I).
Bartlett, George B., M.R.C.S., 1906(E).
Basil-Khan, Minas M., M.B., 1883(S).
Basu, Sir Kailas C., Kt., C.I.E., O.B.E., L.M.S., 1895(Col).
Bates, Herbert, M.B., 1901(E).
Baylor, Robert J., L.K.Q.C.P., 1880(I).
Bayumi, Mahmud, M.R.C.S., 1915(E).
Beale, Thomas M., M.R.C.S., 1899(E).
Bearblock, Arthur, M.R.C.S., 1920(E).
Beards, Samuel A., M.R.C.S., 1924(E).
Beasley, Henry C., L.R.C.P., 1893(I).
Beattie, William P., M.B., 1904(S).
Beddoes, Thomas P., M.R.C.S., 1884(E).
Bell, Francis G., *M.C.*, M.B., 1910(S).
Bell, Mary C., M.B., 1903(E).
Bell-Smyly (Mrs.), Eileen M., M.B., 1917(I).
Belton, Cassius W., L.R.C.P., 1882(S).

THE TREATMENT OF RHEUMATISM IN GERMANY.

A VISIT TO SPAS AND CLINICS.

A PARTY of 20 Englishmen has recently been to Germany to study the methods of treating rheumatic patients, and the organisation for insured patients, in the German cities and spas. The party included representatives of a committee of the British Red Cross Society, the International Society of Medical Hydrology, and several of the English Approved Societies.

In Hamburg, Berlin, and Dresden, it was found that the so-called "rheumatic diseases" formed the great majority of those under treatment by physical remedies. Some of the best known clinics, such as Prof. E. O. Plate's at Hamburg and Dr. August Laqueur's at Berlin, are special departments of general hospitals. They include (1) a complete hydrological installation, with various methods of treatment by friction baths and douches, steam and hot air; and (2) apparatus for light baths and electrical and mechanical treatment. There are, however, in these and other cities a number of other institutions, some of them very large, established by the public insurance organisations (sick-clubs), in which physical treatment is the main feature. To these institutions all kinds of minor cases, both surgical and medical, are referred by insurance practitioners for treatment, and advice is given in many specialised subjects. At some of these "ambulatoriums," to which no beds are attached, 800 cases or more are treated daily.

The visit to Berlin was timed to enable the party to take part in the inaugural meeting of a German committee that has been formed to promote research upon, and treatment of, rheumatic diseases. This was held on August 2nd at the clinic of Prof. A. Bier, under the chairmanship of Prof. Dietrich (Berlin). Among those present were Prof. Bier, Prof. Hoffman, Prof. Kuttner, Dr. Zimmer, and Dr. G. Hauffe (Berlin), Dr. W. Krebs (Aachen), Dr. J. van Breeman (Amsterdam), and Dr. Fortescue Fox, Dr. D. A. Coles, Dr. M. B. Ray, Dr. Hector Munro, Dr. C. E. Sundell, Dr. W. S. C. Copeman, Dr. Maurice Shaw, and Dr. M. Mautner (London), besides representatives of the Railways, Coöperative, Building, and other English approved societies. A paper on the facilities at present available in Germany for the physical treatment of insured persons was read by Dr. Max Hirsch (Berlin). The new German organisation will form a branch of a central committee on rheumatism established by the International Society of Medical Hydrology.

After this conference the medical representatives from England and Holland visited a number of spas which are chiefly concerned in the treatment of rheumatism. Their object was to observe: (1) the methods of treatment actually in use; (2) the various arrangements made for industrial patients, both men and women, at the health resorts, and (3) the existing facilities for medical research in rheumatic diseases. Considering the large numbers of incipient and chronic cases of all forms of rheumatism gathered together at the spas and the city clinics, they also had in mind the possibility of instituting further systematic research to be carried out concurrently with treatment. To assist in their investigations the relevant facts and figures were freely placed at their disposal in the course of many conferences with governmental and municipal spa authorities, officers of industrial societies, and spa practitioners. They found that in regard to special research good work had already been done, whilst

more was in contemplation. A well-equipped institute of balneology, supported by the municipality, has been opened in the present year at Wiesbaden under the direction of Dr. Harpreder, and research laboratories are being added to the Landesbad at Aachen.

In Germany the problem of rheumatism arouses deep and widespread interest. Not only are the many industrial organisations, the public health authorities, and the spa practitioners concerned with it, but also the medical profession as a whole, and the spa federations and municipalities. The problem itself is in many ways the same as in England, and the information gathered in Germany is likely to be of considerable value in this country.

PUBLIC HEALTH IN 1926.

SIR GEORGE NEWMAN'S REPORT.[1]

THE annual report of the Chief Medical Adviser to the Minister of Health must of necessity, as Sir George Newman remarks in his summary, consist of a body of extremely varied, in fact almost miscellaneous, information and opinion. "The progress of a nation's health," he observes, "is . . . a passage through the centuries, and founded mainly on an exclusive regard to the immediate interests and problems of human survival. We are dealing with the proposition of remaining alive in the world, of enlarging the content of life, of increasing its capacity. . . . Can any enterprise be greater? . . . There is hardly a department of the State which will not, consciously or unconsciously, make a contribution to the condition of the public health."

Sir George Newman stresses as the very foundation of the nation's welfare the sanitary duties laid upon local authorities, and enumerates the seven services in which the science and art of preventive medicine have expressed themselves during the last generation. These are: Ascertainment of the situation (notification, &c.); maternity and child welfare; school medical services; national health insurance; Poor-law medical services; Factory Acts; and a series of special means for direct attack upon some of the more insidious and incapacitating maladies, such as small-pox, tuberculosis, venereal disease, and mental decay. He affirms his belief that these seven activities have changed the face of England and, moreover, for all their limitations and imperfections, they have been copied all over the world. "In spite of an enormous increase of population," he says, "without increase of home territory, the total death-rate and infant mortality-rate of the nation have been halved inside our generations. The mortality of childhood is one-third of what it was 80 years ago, and the expectation of life to-day is 17 years longer than in 1876. . . . Never before in the history of this country has so much been attempted by the State on behalf of the health of the people as now. . . . We have in England to-day such opportunity as we have never had before to conquer preventable disease and to ensure personal health and increased capacity." Sir George Newman speaks warmly of the value of health propaganda, even though it is often unbalanced and ill-informed; he cites as its chief fault a lack of sense of proportion, a criticism which we have had to make with some frequency in these columns.

Vital Statistics.

The report commences with a review of the vital statistics, and summarises the report of the 1921 census, recently issued. The indirect results of the war in belligerent populations were as serious as the direct effects. For instance, the proportion of males aged 20–40 fell between 1911 and 1921 from 155 to 141 per 1000. The birth-rate for 1926 was 17·8, the lowest on record, but this country is nearer the neutrals than Germany owing to its favourable infant mortality-rate, reduced last year to 70 per 1000, and thus representing a saving of 40,000 lives above the average. The daily ebb and flow of workers in and out of the metropolis has an important bearing on the spread of infectious diseases. The death-rate in 1926 was 11·6 per 1000, representing 19,037 fewer deaths than in 1925. Increase in the mortality from diphtheria, cancer, and diseases of the heart was more than counterbalanced by the decline in deaths from influenza, pneumonia, bronchitis, and the diseases of infancy. The death-rate in the first four weeks of life and among illegitimate babies still calls for improvement. All classes suffered badly from whooping-cough, and the incidence of diphtheria, poliomyelitis, and small-pox showed an increase. In England and Wales during 1926, among insured persons alone, a total of 28¼ million weeks' work (the equivalent of 12 months work of over 540,000 people) was lost through sickness. The labour and expense entailed in the care of these people, and the fact that they were breadwinners for others, must be remembered in assessing the loss to the nation.

Accuracy of Statements of Causes of Death.

In discussing death certification the report maintains that official records of mortality suffer from serious and remediable defects, falling under two headings:—

(1) Relevant information throwing light upon the real cause of death is available but not presented; thus, deaths from motor accidents have almost doubled in six years, although the ratio may not have increased; but there is no analysis of the mishaps, and we do not know how many of the 3368 victims were drivers, passengers, or pedestrians respectively. Here is an example where exact information is available, but is not disclosed. Dr. Stevenson's investigation reveals that it is the three- or four-wheeled vehicle which kills small children; the well-braked tram is safer than the car, and the mobile motor cycle is more dangerous to its rider than to the pedestrian. A decline in mortality should therefore accompany improvement in brakes.

(2) Information is not available and ignorance may be disguised by verbalism. Many of the deaths ascribed every year to cancer of the liver and gall-bladder must in reality be due to primary growths in other organs, and any attempt to measure the effect of means of treatment are seriously prejudiced by this laxity in certification. There is no doubt, the report holds, that our knowledge of the real toll of human life taken by alcoholism would be appreciably extended by a confidential death certificate.

Discussing *status lymphaticus*, the report asks pertinently what means practitioners have of knowing if the thymus of a person who has died suddenly is or is not enlarged. Prof. J. A. Hammar's recent monograph reveals an enormous range of weight within strictly normal material. Status lymphaticus, to quote Prof. M. von Pfaundler, has been denatured into a "pandiathesis." To diagnose it on thymus weight alone is unscientific. This is not to say that there does not exist a human type prone to die suddenly without adequate cause; the type was recognised hundreds of years ago, but the attempt to provide precise anatomical criteria has failed. The term "status lymphaticus" on a death certificate is characterised as an example of the misuse of the jargon of endocrinology, nutritional chemistry, or psycho-analysis to explain the origin of symptoms and signs. Sir George Newman considers that it is hardly too much to say that the fabric of the art and practice of preventive medicine is founded upon the accuracy of the registration of the cause of death. Unless and until a nation has adopted a sound system of vital statistics—the book-keeping of humanity—there can be no evaluation of assets and liabilities.

Epidemiology.

In 1926 10,146 cases of *small-pox* were notified, the most striking feature being the very large number of cases [2] in the county of Durham. The report states

[1] H.M. Stationery Office. Pp. 281. 3*s*.

[2] See THE LANCET, 1926, ii., 1175; 1927, i., 39; 1927, i., 238.

clearly that the time has come for the public to choose between small-pox and vaccination, and to realise the difficulties attending the control of the present mild outbreak. Small-pox, severe or mild, is a menace which should be prevented; our duty is to rid the country of it, and successful vaccination and re-vaccination constitute an efficient protection.

There were 2739 cases of enteric, a decrease of 40 on 1925, two cases of bubonic plague, one of typhus, no cholera, but an increase in dysentery.

A report has now been issued giving exhaustive analysis of the information yielded by the inquiry into *scarlet fever*. The Committee concluded that there are not sufficient grounds for prescribing a routine period of detention in hospital of more than four weeks for uncomplicated cases; that hospital and home treatment must play a fundamental part in a well-ordered public health system; that some of the accommodation reserved for scarlet fever might be better used for pneumonia, measles, or influenza; and that current rather than terminal disinfection is the more rational procedure. The report speaks very hopefully of the prospects of the Dick as well as of the Schick processes.

There were 51,069 cases of *diphtheria* during the year, with 2994 deaths, a serious burden of disease and mortality. Local authorities are advised to aim primarily at offering protection to the pre-school population through infant welfare or special clinics; it is essential for the organisation to be prepared beforehand, the staff trained and public opinion enlightened. The vast majority of parents are still completely ignorant of the possibility of protection. The large increase in mistaken diagnoses in London can be taken fairly to suggest that greater care is being taken in notifying suspicious cases.

A slight, mild epidemic of *influenza* broke out in London early in 1926 and spread slowly northwards. The death-rate was low, mainly due to bronchial pneumonia. Convalescence was rapid, but often accompanied by persistent cough. Among the researches carried out under the Auxiliary Scientific Investigation Fund was the prosecution of a study of the respiratory flora of apparently normal persons, in the hope of elucidating some of the problems of epidemic influenza. There was no increase in the pneumococcus during the late autumn of 1925, although there was some increase in Pfeiffer's bacillus. In 1926 the situation completely changed; the pneumococcus rose from under 10 per cent. to 60 per cent. between October and November, and remained up till the end of January. Pfeiffer's bacillus also increased, less notably, but in January suddenly became very prevalent. It thus appears that a sudden increase in the frequency of healthy carriers of pneumococci precedes an epidemic manifestation of influenza.

Infections of the Nervous System.

While the reported prevalence of cerebro-spinal fever and encephalitis lethargica was less than that of 1925, there was a very striking increase in poliomyelitis and polio-encephalitis, the notification figures exceeding all previous records. The report does not think it safe to assume that this presages a continued decline in the incidence of encephalitis lethargica, and finds even less reason to ascribe the improvement to any human intervention. An inquiry into the nature and amount of resulting disability has been held, and will, it is hoped, provide a reliable guide to the best after-treatment. The encephalitis unit at Winchmore Hill seems likely to prove most useful as a clearing house for observation, classification, and allocation. The work of departmental officers on the subject is summarised.

A special chapter is devoted to acute poliomyelitis on account of its excessive prevalence during the year. The history of the disease and of the 1926 outbreaks is reviewed. The conclusion arrived at is that Wickman's original findings in favour of contact transmission have been amply confirmed. Sufferers from an acute, mild, or atypical form, healthy persons who have been in contact, and chronic carriers who have apparently quite recovered, may all convey the infection. There is no satisfactory proof of natural transmission by biting insects or by milk. It must be remembered that the incubation period varies within wide limits, and that many cases are never notified. Three out of the five outbreaks occurred in districts accessible by sea or river, and infection may have been conveyed to Kent from Brittany. The term "infantile paralysis" is condemned as a misnomer and the disease defined as "an acute infectious fever which may or may not proceed to invasion of the nervous system." The pathology, symptoms, diagnosis, and treatment are reviewed and commendation given to Walshe's three-stage classification—i.e., (1) general infection, (2) subarachnoid invasion, (3) involvement of the grey matter. The essential of treatment is said to be coöperation between medical officer of health and local practitioners, and improvement in notification is urged. A review of treatment measures indicates that, if paralysis occurs, permanent crippling can only be avoided by prompt and long-continued orthopædic treatment, which should be secured as part of the scheme for maternity and child welfare.

Cancer and Tuberculosis.

The mortality-rate per million was 961 for tuberculosis and 1362 for cancer. The work of the departmental committee during the year included investigations into the statistics and radiological treatment of cancer of the breast and uterus, and into the value of serological tests for diagnosis. An unusual research compared 500 patients of cancer of the breast with 500 controls; it showed that many supposed predisposing conditions had no influence in encouraging cancer. The predisposing significance of injury, infertility, and chronic mastitis was confirmed. The urgent need for further information leads to the suggestion that clinical notes should be supervised by someone of greater experience than the student, and that efforts be made to obtain and maintain records as complete as possible. A form of follow-up system is being instituted in the large county borough hospitals, and it is hoped to extend it. All clinical data collected are submitted to careful analysis, and if the deductions are adequately supported a report is prepared for the use of the profession. Six such reports and five circulars to public health authorities have been issued.

The returns of medical officers of health indicate that there is still room for further improvement of notification of tuberculosis; many cases are not notified before death and still more only during the last six months of life. The decline in the number of deaths from phthisis is gratifying but unexplained, save as the result of the public health campaign. On Feb. 1st, 1927, there were 442 dispensaries in England, 69 special centres, and 367 tuberculosis officers. The work has advanced considerably in most districts; there is increased coördination under orthopædic schemes and with school medical officers; X ray diagnostic installations have been provided at many dispensaries and private doctors show increasing readiness to send cases. There is need for careful comparison of the results of sanatorium and home treatment. Experience has shown that adults cannot be trained in new occupations, and that treatment must be followed by a long period of safeguarding, most effectively secured in village settlements. Such provision as is made by the "Factory in the Fields" and the Hull Care Committee may prove useful. The time is considered ripe for a few colony schemes to be tried experimentally. The second report on "sanocrysin" from the Medical Research Council[3] concluded that it is of value in certain carefully selected cases only. The Calmette method is being investigated.

Venereal Disease.

At the close of 1926 there were 190 treatment centres in England and Wales; the ratio of attendances to cases showed a further increase during the year. Careful follow-up work has reduced the number

[3] THE LANCET, 1926, ii., 181.

of defaulters, and the location of centres apart from hospitals does not seem to deter patients. A warning is sounded against inadequate treatment. A short course of arsenobenzol and mercury is often followed by relapse, and it is important that medical officers should be convinced of the necessity for prolonged treatment. Practitioners are reminded that the signs of venereal disease in pregnancy are often absent or very slight, and are urged to follow up the clue given by infected children or stillbirths. Treatment of the congenitally syphilitic child, also, should be commenced while the disease is latent and doctors should act on suspicion. Experience in Plymouth has shown that detection of the disease before it is manifest would considerably raise the standard of health of the population.

Maternity and Child Welfare.

This work has been expanded and the gloomy forebodings as to the effect of the strike on the physique and vigour of school-children were not fulfilled, partly as the result of provision of meals at school and the distribution of free milk. The maternal mortality-rate was 4·12, a slight rise. The importance of making provision for treatment of puerperal pyrexia and for antenatal supervision is stressed. There are now 772 antenatal centres, 105 homes for unmarried mothers, and 2324 infant welfare clinics. The report remarks that money expended on centres and health visitors brings perhaps a greater return than any other form of expenditure on maternity and child welfare, and points out that the Adoption of Children Act, 1926, may prove prejudicial to the welfare of illegitimate children, whose foster mothers may adopt them to avoid supervision. Although provision for ophthalmia neonatorum is good in most areas there still seem to be administrative loopholes, and the responsibility for notification has now been laid wholly on the medical practitioner.

The care of the pre-school child is described as a problem awaiting satisfactory solution. Dr. Margaret Hogarth's examination of 1000 unselected children of 3 years of age revealed a large amount of preventable disease, but also created an impression of a much higher standard of parental care than was evident ten years ago. The most striking feature was the prevalence of rickets, the forerunner of all that is required to produce a C3 nation. The effects of treatment by sunlight and cod-liver oil appear to wear off when the course is discontinued. Diseases of the throat, nose, and ear formed an important group of defects, and the prevention of otitis media and of the sequelæ of enlarged tonsils and adenoids alone make systematic supervision desirable. Special attention is drawn to the danger of forgetting the mental development of the child through focusing attention on his physical welfare. The Conference on Child Welfare, held at Geneva in September, agreed to investigate the value of preventive measures against scarlet fever, diphtheria, and measles, to prepare a note on the arrangements in different countries for the training in pediatrics of doctors, nurses, and health visitors, and to hold an inquiry into infant mortality in selected districts over a period of 12 months. The areas chosen in England were Sunderland and parts of Staffordshire (high rate); Croydon and Oxfordshire (low rates). This is the first international inquiry of the kind, and is to be clinical rather than statistical.

National Health Insurance.

The number of persons entitled to benefit in 1926 was 14,102,000, one-third of the population, breadwinners on whose health and capacity the living of the great majority of the remainder was dependent. Increase in the number of certificates during the strike and in the aggregate cost of prescribing are commented on. Late in the year six full-time regional dental officers were appointed and dental benefit is now almost universal. More than £400,000 a year has been allocated to ophthalmic benefit. The statement that the service "does not tend to the prevention of disease" is strongly combated and the educational work carried on by panel committees is reviewed.

Food in Health and Disease.

Gratification at the awakening of public interest in diet is expressed, and caution and discrimination in making didactic statements are called for. Recent research has shown that the keynote of a successful diet is variety and has thrown doubt on the belief that primitive man was better off in regard to his diet than man of the present day. It is pointed out that this country is eminently suited to the production of the essential foods, milk, and vegetables, and that they should be distributed widely and cheaply enough for them to be in everybody's daily diet. Describing the improvements in milk preparation the report states that there has been a satisfactory increase in the amount of Grade A (T.T.) milk supplied. Great stress is laid on coöperation between M.O.H., public analyst, and sampling officers. There is immense and continuing improvement in purity of foodstuffs, and more tests for preservatives were carried out during the first two months of the year than during the whole previous decade. Analytical methods need revision, especially for traces of boric acid, and this has been the main work of the laboratory. Forty-eight food-poisoning outbreaks are reviewed.

Research Work.

Work on the hæmolytic streptococci has been published and supports the view that these organisms are the cause of scarlet fever. Some research on pneumococcal virulence and immunity will be completed shortly. A good deal of statistical analysis was done for the Scarlet Fever Committee and on school anthropometry. The factors in puerperal mortality have been investigated, as have also the incidence of disease in cotton-spinners in wet and dry sheds, and health in the printing industry. It is becoming clear that the conception of herd immunity as distinct from individual immunity is a very important one for prophylaxis. The steady increase in the number of requests for advice and help in research work arising out of the ordinary duties of medical officers is viewed with great satisfaction as the most valuable work of the department. A review of progress in artificial light treatment lays stress on the necessity for medical control and supervision. A disquieting increase is noted in the deaths from anæsthesia, and the Ministry is anxious to ascertain the real fatality ratio and to relate it to different anæsthetics and methods of administration.

International Health.

The report concludes with a review of the work of the League of Nations Health Committee, the Office International, the International Sanitary Conference in June, and the International Pacific Health Conference.

Other chapters deal with the Port Sanitary Authority and the Poor-law.

THE SPREAD OF TUBERCULOSIS.

EXAMINATION OF CONTACTS.

THE eradication of tuberculosis depends on the solution of a problem that has hitherto baffled an army of investigators. The problem is concerned with the manner of its spread. A husband, for instance, is consumptive; his wife, subject to daily and nightly opportunities for infection, apparently escapes the disease. One child, perhaps, dies of miliary tuberculosis, two or three children become "tuberculous seedlings," and after a school career, chequered by frequent visits to clinics, dispensaries, and sanatoriums, reach adult life without revealing any obvious signs of tuberculous disease. In another similarly infected family, by contrast, the children pass through school life apparently free from disease, but when adolescence is reached, one or more of them suddenly develops signs of active phthisis, possibly many years after the death of the consumptive parent. In some cases the tragedy of "Wuthering Heights"

is repeated and a family is decimated; in others a single member of the second generation succumbs. Not infrequently, again, an adolescent or young adult develops phthisis although the family bill of health is clear of any taint of the disease and no source of infection can be traced. The origin of the chronic fibroid type of tuberculosis common in later life is equally uncertain, and it is often doubtful in any particular case whether the infection is of recent date or whether declining vitality has caused a smouldering fire to blaze.

Where much is obscure certain facts are patent. That a member of a family suffering from manifest tuberculosis is a grave source of danger to all its members has been recognised since Koch's discovery, and, indeed, was recognised before it, and provision for the examination of contacts is considered to be an essential part of all antituberculosis schemes. When a case of tuberculosis is notified a health visitor calls at the home of the sufferer, and though the adolescent members of the family are apt to decline to attend the dispensary, maternal anxiety can usually be depended upon to produce two or three infants or children of school age. These are martialled before the tuberculosis officer, a physical examination is made, the signs of manifest tuberculosis are lacking, and a much-relieved parent returns with her wondering offspring to the home where infection abides. Finally, a record of negative results for the contacts is duly returned to swell the satisfactory statistics of the county medical officer, regardless of the fact that to pronounce an infant "free from any trace of the disease," because auscultation and percussion fail to reveal obvious signs of tubercle is about as useful as to palpate its chin and report that there is no evidence of a beard.

The familial spread of tuberculosis can never be prevented by such perfunctory methods and slipshod work. It is notorious that pulmonary tuberculosis is only recognisable by physical signs in the chest when the disease is firmly established. The "early case" of the sanatorium is not an early case of tuberculous infection; the sound of cracking timbers, the fall of decayed masonry are not the signs by which a housing inspector determines incipient decay in a building. For too long the threatenings of imminent collapse have been mistaken for the first warnings of danger. The slogan of the propagandist, that consumption is curable in its early stages, is only true if applied to stages whose detection requires far greater delicacy than that of palpation, percussion, and auscultation.

In this connexion the work of E. L. Opie and F. M. McPhedran,[1] of Philadelphia, deserves more attention than it has yet received in this country. Their investigation of tuberculous contagion in families has been based upon evidence obtained from the intracutaneous tuberculin test, correlated with information from skiagrams, and supplemented by the usual physical examination. In this way both contact and non-contact families have been subjected to a searching examination, the results for each family being set out on an ingenious record card showing diagrammatically the condition of each member as revealed by the various tests employed. The age of each member is also shown and the duration of exposure to infection in the case of "contact" families is graphically indicated.

The tuberculous are divided into (*a*) those with manifest disease recognisable by physical signs, sputum tests, &c., and (*b*) those with latent disease only revealed by radiographic examination and tuberculin tests. Latent infection in the child is due to implantation of the tubercle bacillus in the lymphatic system of the lungs and is revealed by nodes in the lung field or by enlargement of the tracheobronchial glands; the radiographic appearance of these foci has been compared with post-mortem findings and their significance has been proved. The adult type of latent infection—which is, however, occasionally found in children—is characterised by involvement of the lung apex, which may be the seat of tuberculous deposits or may exhibit a thickening of the apical cap. It is claimed that the X ray findings are confirmed by the intracutaneous test, though the latter is more delicate and supplies evidence of infection at an earlier stage.

If the conclusions of Opie and McPhedran are correct, they ought to be generally applied as far as may be possible. They are as follows:—

1. When latent tuberculosis is taken into consideration, tuberculosis exhibits the characters of a contagious disease and affects all children of households within which some members, suffering with tuberculosis, scatters tubercle bacilli.

2. Recognition of latent apical tuberculosis has demonstrated that tuberculous infection is transmitted to adults and to adolescent children, and has shown that approximately one-half of the partners of husbands and wives with open tuberculosis are infected after marriage.

3. Duration of exposure to open tuberculosis is an important factor in determining the character and severity of the resulting infection; in instances of recognisable tuberculosis of tracheobronchial lymph nodes the average duration of contact with tuberculosis has been approximately four and a half years and instances of latent apical tuberculosis nearly twice as much.

4. Dispensaries for the care and control of tuberculosis should be organised so that spread of latent infection within the family may be recognised and prevented. A chart for each family, depicting the severity of latent and manifest disease disclosed by quantitative tuberculin reactions and roentogenological examination, will forcibly direct attention to effective means of control.

5. Latent tuberculosis often becomes manifest. Certain forms of latent infection foretell the approach of clinically recognisable disease. These are (1) infection recognisable by the tuberculin reaction during the first two years of life, (2) tracheobronchial tuberculosis in children recognised by roentogenological examination, and (3) latent apical tuberculosis in adolescent children. Children with these forms of tuberculous infection should be examined at frequent intervals and treated as though they had recently arrested tuberculosis.

6. All adults in whom latent apical tuberculosis has been recognised should receive the same care as patients with arrested phthisis.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Abortion in Russia and in Germany.

THE Breslau Medical Society recently discussed the consequences of legalised abortion in Russia. The new legislation in that country recognises no difference between children born in and out of wedlock, and the Soviet has decreed that any abortion sanctioned by a medical commission and performed in a public hospital by a doctor will not be regarded as criminal. As a result of this decree so many women applied for abortion that the hospitals were soon overcrowded and private sanatoriums had to be used. The Soviet authorities intended that abortion should no longer be concealed, and that women who wished their pregnancy to be interrupted should be able to get this done under favourable circumstances. They wanted to prosecute those who make a business of artificial abortion, and not the mothers who seek to have the operation performed. Needless to say, the result has been a great increase of abortion, and according to Dr. Niedermeyer, who opened the discussion, only a nation of such vitality as Russia can stand such legislation. Abortion performed by

quacks for money is now rare, though it has not yet disappeared. Septic complications have very much decreased, as abortion in the great majority of cases is performed under hygienic conditions. This is, however, the only favourable aspect of the new regime. It is stated that repeated abortion causes various troubles, and Russian gynæcologists in this connexion report injuries to the uterus and neighbouring organs, concretions which have produced severe complications at later pregnancies, and mental disturbance. Placenta prævia and atony of the uterus during labour have become more common. Dr. Niedermeyer warned Germany not to follow the Russian example.

In the discussion Dr. Rosenfeld stated that although artificial abortion is a criminal offence in Germany, nevertheless about 500,000 abortions are performed annually—some even put the figure at 800,000—and only 1000 to 2000 offenders are prosecuted. The number of cases in which pregnancy is prevented by contraceptives and pessaries cannot be ascertained by statistical means. Germany has, notwithstanding, an annual surplus of more than half a million. Since legislation against artificial abortion is thus ineffective, it is desirable that it be performed not by quacks but by qualified medical men. Prof. Fraenkel, head of the gynæcological clinic at Breslau University, said that abortion, even if performed under the most favourable conditions, led to disease much more frequently than did normal birth. Leaving aside all political and social arguments, he warned the faculty against performing abortion on other than strictly medical grounds.

Under the present German criminal law interruption of pregnancy is always a crime, no exception being made for medical men, even if it is urgently necessary in order to preserve the life or health of the mother. Prosecution of medical men has been rare, but has occasionally been proceeded with on anonymous and other information. It is therefore satisfactory that the High Court at Leipzig has lately given a judgment which will protect medical men against these unpleasant incidents. The opinion of the medical profession, and of some legal authorities also, that a special professional right exists to interrupt pregnancy on urgent necessity is not maintained by the High Court, and a verdict of "not guilty" has been given on other grounds, less comprehensible, but none the less satisfactory to the medical profession. The court states that the interruption of pregnancy by a medical man may be technically criminal abortion . . . but that there is no criminal offence unless there is also criminal intent. The life of the mother must be valued higher than the life of the child in the womb, and if an abortion is the only chance of saving the mother's life it is not to be considered criminal. It may be noted that the new criminal bill now under consideration contains a clause that artificial abortion is not criminal when performed by a qualified medical man who considers that according to the principles of medical science no other course can save the life or the health of the mother. The same principle holds good for perforation of the skull during childbirth.

Congress of Sick-Clubs.

The annual congress of sick-clubs under the Workmen's Insurance Act was held this year at Königsberg, where 1400 delegates met, representing 1½ millions of insured persons; the government was also represented. The president alluded to the care taken by the clubs not only of the sick, but also of convalescents and children; he also mentioned the agitation against the clubs in a sentence which, without mentioning the medical profession, was obviously directed against its leaders. Dr. Stein, of Geneva, spoke on the international insurance of workmen, and Prof. Adam invited the clubs to assist the work of the Association for Health Instruction; a resolution in favour of Prof. Adam's proposals being unanimously adopted. Other addresses urged the clubs to assist in the campaign against venereal disease, infant mortality, and occupational diseases. The meeting one more showed the strength and importance of the clubs. Their position has, unfortunately, been won partly in the face of medical opposition and to the prejudice of the profession.

X Rays in Hospitals and in Private Practice.

In Germany there is a marked tendency among the public to underestimate the work of private medical men, and to resort as much as possible to hospitals and sick-club institutions. The public believes that these institutions have more modern methods of cure than the average medical man or the private specialist, and that treatment is more effective if given at places where there is a large staff. So far as X rays are concerned this opinion is refuted by a recent statistical record, in which the injuries to patients in public and private institutions are compared. Of the 19 genuine recorded cases of damage due to X rays used for diagnostic purposes, 16 occurred in public institutions and three in private practice. Two of the cases were due to negligence and 17 to insufficient knowledge. Of 59 genuine cases of injury in the therapeutic application of X rays, 29 occurred in hospitals and public institutions, and 30 in private medical institutions. It is stated that in 22 of these cases the medical man was in no way to blame, but that in 15 cases negligence, and in 23 insufficient knowledge, must be supposed, the cases being divided equally among hospitals and private institutions. About 45 cases of injury were recorded in hospitals and sick-club institutions, where the work is often done by young doctors or even by nurses. The private practitioner, on the other hand, has to do the work himself and on his own responsibility. The injuries caused by Rontgen rays were severe; ten cases were fatal, and amputations were necessary in others.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1926 statistics of six towns, five county boroughs, and one borough:—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Diarrhœa under 2 years.	Infant mortality.	Maternal mortality from childbirth.
Bristol (383,300)	17·3	11·4	1·13	1·24	1·9	1·6	6·0	70	3·5
Croydon (205,900)	16·9	11·0	1·01	1·60	1·5	1·3	7·5	61	7·0
Coventry (127,800)	16·5	10·3	1·15	1·13	1·5	1·1	4·7	69	4·7
Bournemouth (90,100)	12·3	13·5	1·04	1·96	1·8	2·5	5·4	58	3·6
Great Yarmouth (57,760)	16·7	11·8	1·05	1·71	1·4	1·6	5·2	58	4·1
Scarborough (39,740)	16·6	13·4	0·95	1·84	1·8	2·7	4·6	71	3·0

Bristol.

Dr. D. S. Davies suggests that just as we have protected the nursing staffs in our hospitals from diphtheria, "so every school and every institution ought to insist upon the protection of its scholars against diphtheria."

Several houses at Bristol have become infested with a mite (*Glycyphagus domesticus*) found in Algerian fibre imported for upholstery. These mites breed rapidly, and carpets, walls, and floors are quickly covered with a fine coating of the insects, like dust. The condition is difficult to eradicate because the mite

has a resistant cystic stage. Dyeing of the fibre appears to destroy it. The British Museum has published a pamphlet on this insect, which suggests that the best way of avoiding the trouble is "to refrain from buying furniture stuffed with Algerian fibre."

The Bristol Corporation Act of 1926 contains a section requiring adequate ventilation for gas geysers. Dr. Davies mentions that there is an idea prevalent that when Bunsen burners are provided a flue is not necessary because combustion is more perfect and the risk of the production of carbon-monoxide is less. He finds, however, that among seven cases of fatal gas poisoning at Bristol the Bunsen flame was used in three, and that it is, therefore, necessary to have a flue fixed in every case. The report contains illustrations of the right and the wrong methods for securing ventilation for geysers.

The increase in the accommodation at the isolation hospital, postponed owing to the war, has now been completed and the 56 additional beds will be brought into use during the current year. Three nurses are employed to visit all kinds of infectious diseases at home. When a first case of measles occurs in an infant department, the class-contacts are excluded from the ninth to the fifteenth day and placed under the supervision of one of these home nurses. Bristol has been fortunate as regards small-pox. During the last 43 years there have been 102 introductions, 23 through the port. The total cases numbered 1243 with 127 deaths. Since 1917 there have only been two introductions, both through the port. One, in 1921, caused seven cases with one death, and the other, in 1924, one case with no death. Dr. Davies thinks that the value of isolation hospitals for scarlet fever is not put fairly when a comparison is made as regards return cases between home treatment and hospital treatment. His experience during the last six years in Bristol shows that 4237 primary cases removed to hospital were followed by 284 secondary cases, whereas 3918 home-treated cases were followed by 513 secondary cases. A chart in the report shows the great increase in poliomyelitis and polio-encephalitis in several of the counties during 1926, Leicestershire and Nottinghamshire being prominent examples. In view of the possibility of a similar increase in Gloucestershire, Dr. Davies gives a list of preventive measures. At a conference of representatives of the health committee, education committee, and board of guardians a resolution was passed expressing the opinion that post-encephalitics cannot be suitably dealt with under the Mental Deficiency Act, and that what is required is a healthy outdoor life under skilled discipline in an institution apart from mentally defective or insane persons. It was also pointed out that there is ample provision for present needs in the Poor-law hospital at Southmead, and that there is no justification for pressing the Ministry to sanction the provision of special accommodation for the Bristol area. Among the 48 notifications of ophthalmia neonatorum were two cases where infants blinded in both eyes were admitted to hospital for treatment from outside the city.

One of the health visitors "is now fully occupied in dealing with cases where increase or re-establishment of the supply of breast milk is desirable and the feeding and management of weakly children." This visitor gives lectures in turns at the 22 schools for mothers conducted by the Bristol Infant Welfare Association. Recommendations for the increase of the number (21) of health visitors are under the consideration of the Ministry of Health.

At the isolation hospital severe cases of scarlet fever improved rapidly with scarlet fever antitoxin, and it is suggested that the favourable mortality-rate—only one death among 515 admissions—may have been due to this cause. Of 50 samples of milk examined for tubercle three gave a positive result.

Croydon.

Dr. H. P. Newsholme reports that the public laboratory, provided jointly by the Croydon General Hospital and the Corporation, began work in April, 1927. The new clinic premises and sick nursery in Lodge-road came into use at the beginning of 192 and has proved a very real success. The nurser on the first floor provides accommodation for 12 ailin children under 5 years, also an isolation cubicle an a ward for two nursing mothers. The ground flo of the building accommodates the various clini required by the education and health committee The opening ceremony was performed by Princes Mary on May 18th, and early in 1927 the gift of mercury-vapour lamp was received from the mothe and workers at the South Croydon Infant Welfa Centre. The number of mothers who attended th antenatal clinic during 1926 was 659. The total birth were 3477.

Arrangements have been made with the Surre County Council for the admission of small-pox cas into Clandon Hospital; this enables the joint smal pox hospital at Cheam to be used as a sanatorium f tuberculosis. The number of beds at Cheam ha been increased from 50 to 85 since April, 1926, an Croydon has 40 of these beds, 25 for men and 15 f women. During the year about 10 per cent. 3874 working-class houses inspected were found t contain one or more overcrowded rooms. In 117 cas it was found possible to abate the overcrowding witho producing overcrowding elsewhere. The municip lodging-house contains 101 cubicle beds and th average number of lodgers was 100 men per nigh The charge is 9*d.* per night and 5*s.* per week. Th receipts for the last three years were £1182, £134 and £1338, and the expenditure £1350, £1485, an £1639.

The following samples of graded milk were examine during the year: Certified, 7; Grade A (T.T.), 5 and Grade A, 9. All of them conformed with th requirements. Out of 247 samples of milk examine for tubercle, two gave a positive result. The chi items of note in the school report are the growth the dental scheme and of the scheme for dealing wi crippling conditions. In April the second whole-tim dental surgeon replaced a part-time dentist. 9393 children examined, 68 per cent. had defecti teeth as against 75 per cent. in 1925 and 82 per cen in 1924. The children dealt with for crippling co ditions numbered 244, 72 from the maternity an child welfare, 132 from the school medical, and 40 fro the tuberculosis departments. The orthopædic clin is conducted by an orthopædic surgeon at the Croyd General Hospital, where in-patients requiring sho periods of treatment are admitted. Those needi prolonged treatment are sent to Pyrford Orthopæd Hospital. During 1926, 11 children were admitt to the Croydon Hospital and nine were sent Pyrford. Dr. Newsholme again draws attention the need for an open-air school for anæmic debilitat children, numbering over 250, who cannot deri proper benefit from education in the ordina elementary schools.

Coventry.

Dr. E. H. Snell reports that an automatic pollution recorder has been in use since Novemb The scheme for a public abattoir has gone a st farther, the Council having approved of the erecti of an abattoir at Whitley at an estimated cost £21,757. The site adjoins the railway. Its area five and a half acres. Two acres is to be utilised once, the remainder being available for extensi The scheme is intended in the first instance to provi accommodation for butchers who have none. T slaughter-houses in existence at the end of 19 numbered 46, 11 registered and 35 licensed. The is already a dead meat market in Barrack-squa The meteorological report shows that the rainf was 27·66 inches and the hours of bright sunshine 11 A chart indicates that the whole of the recent decli in infant mortality has occurred between the ag of 4 weeks and 12 months, and that the neona mortality has been practically stationary since 19 In the more recently developed portions of the c separate sewers have been installed for foul a surface water. An important scheme for laying furth

storm-water relief sewers has now been approved by the Council.

It was only possible to deal adequately with very serious cases of overcrowding owing to the shortage of houses. Details are given of eight such cases, of which we give the last: "The house contained one living-room and one bedroom. The bedroom, containing 1118 cubic feet, was occupied by a man, wife, four daughters aged 15, 7, 3, and 1 year, and four sons aged 14, 10, 9, and 5 years respectively."

The milk-supply in 1926 averaged 4700 gallons per day and exceeded demand, nearly half the total quantity is pasteurised and sold in bottles. One of 2 specimens of milk from 39 farms was found to contain tubercle bacilli, and as a result two cows from an outside farm were found to be tuberculous and were slaughtered. A table, which has been compiled since the Council first provided sanatorium beds, shows the present condition of the ex-sanatorium patients. Thus, of the 956 patients treated during the ten years 1909–1918, 240 were known to be "remaining well" at the end of 1926. The tuberculosis officer, Dr. J. McG. Williams, reports that, from the summer of 1925 to the end of 1926, 50 patients were treated with sanocrysin at the Memorial Sanatorium, and that 12 had completed their treatment. In five cases the treatment was unsuitable and discontinued, 22 patients improved, six showed no improvement, three became worse, and six died. If the improvement in the 12 patients is lasting, says Dr. Williams, it may be concluded that sanocrysin is beneficial in certain cases, but years must elapse before the final results can be judged with accuracy.

The percentage of patients who keep up their attendance at the venereal diseases clinic has improved from 82·6 to 86·7 per cent. The infant welfare centres are being used both for the instruction of school-girls between the ages of 13 and 14 and for pupil-midwives; 41 school-girls attended during 1926 and eight pupil-midwives. An antenatal clinic is conducted by a gynæcologist, Dr. S. A. Ballantyne, at one of the welfare centres. Of the 251 cases seen 233 were booked for maternity hospitals, eight were sent by midwives, eight came of their own accord, and two were not pregnant. The total births in Coventry during the year numbered 2116.

Bournemouth.

This report is issued under the name of the late C. A. D. Edwards, the medical officer of health. The public analyst, Mr. R. A. Cripps, points out that the three samples of cream sent to him contained only 25 per cent. of fat, "or rather less than half that usually found in cream." He thinks that the Ministry should issue an order defining cream as containing from 40 to 70 per cent. of fat, and compelling the vendors to state upon the label the approximate proportion of contained fat. Of the 18 samples of sausages examined six contained sulphur dioxide and four boric acid. Since Jan. 1st, 1927, the use of boric acid has been prohibited.

Great Yarmouth.

Dr. A. N. Stevens reports that there is no shortage of midwives and that it is customary for medical practitioners to be engaged for confinements. Over two-thirds of the births during 1926 were attended by medical men. Only 75 per cent. of the total live births were notified to the medical officer of health. Of the infants visited during the year, 82 per cent. were found to be breast-fed during the first month, 61 per cent. during the fourth month, 59 per cent. during the eighth month, and 34 per cent. during the twelfth month.

Scarborough.

Dr. S. Fox Linton reports that 139 new houses were built during 1926, as compared with 332 in 1925. The houses built with State assistance numbered 93, as compared with 296. Housing conditions are bad in part of the town. The area represented as unhealthy by the medical officer of health in January, 1924, has not yet been dealt with. The corporation subsidise one bed at a nursing home for maternity cases, the cost being a retaining fee of £5 and £4 4*s*. per week when the bed is occupied. Twenty patients used the bed for a total of 41 weeks. The question of adopting the model by-laws for slaughter-houses is being discussed. Dr. Linton's report in favour of the use of the humane killer shows that there is little or no objection to the use of a humane killer for cattle and sheep, and that the objection in the case of pigs appears to be negligible. There are slaughtering establishments in Sweden which specialise in exporting, and from which bacon is exported to England, where humane killing is obligatory. Among adverse sanitary circumstances Dr. Linton reports the existence of about 920 houses with privies, and an unknown number of privies attached to houses with water-closets. Four-fifths of the refuse is disposed of by tipping and a tip close to the new corporation housing estate has caused complaints during the year. Six samples of bread and butter were obtained at local restaurants and in three instances were found to consist of bread and margarine. Fines of £3 each were imposed. The hours of bright sunshine totalled 1412, or about 50 hours less than the annual average for 35 years.

SCHOOL MEDICAL SERVICE.

THE following is a summary of the three school reports under notice:—

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
Nottingham .	40,838	35,547	11,551	25,704	17·4
Shrewsbury .	4,000 (approx.)	3,896	1,178	7,726	9·2
Carlisle.. ..	8,029	7,044	2,724	6,215	20·7

* Excluding uncleanliness and dental defects.

City of Nottingham.

A feature of the report by Dr. E. M. Wyche, senior medical officer (education), is an illustrated account of orthopædic work in the city. Mr. S. A. Malkin, the orthopædic surgeon, says that "not the least gratifying feature of the year's work has been the fact that some of the children who last year attended for orthopædic treatment have this year left school fully able to take their place in the business and industrial life of the city . . . . But for the committee's orthopædic scheme, many of their disabilities, now happily removed, would necessarily have been neglected until complete breakdown and much needless suffering had occurred. No less than 63 children have been discharged cured—a permanent gain to the community as well as to the individual concerned." This useful work will shortly be facilitated by the establishment of a country hospital school. The city can be justly proud of its open-air schools. The combined accommodation is for some 385 children, which seems generous in comparison with that of many other towns, but there is need for substantial increase in the south-east part of the city. Dr. Wyche gives in a few lines a summary of the history of school health work in Nottingham since 1907, each year or two showing some development. Even now, he says, not less than one-fifth of the school population is found defective from one cause or another, many of which should not be allowed to continue. It is often forgotten, moreover, as he points out, that these figures give a somewhat optimistic view, since they take no note of children who are at home ill, or in special schools and institutions. On the other hand, an apparent rise in incidence of defect may be due to exceptionally thorough investigation which will bear fruit later.

The consultant aural surgeon, Mr. H. Bell Tawse, welcomes the opening of a new department in a clinic,

and remarks that "now the medical officers see their own cases up to and through the stage of operative treatment and subsequently can follow their progress up to complete recovery. The progressive widening of the scope of the medical officers' duties, and the improvement of the conditions of service, are matters of infinite importance; it is in this way only that the committee can obtain the best and keenest types of recruits to fill vacancies in their medical staff. Entrusted to capable hands, the school medical service should become our most effective instrument for the prevention of needless disease and disability.

Shrewsbury.

Dr. A. D. Symons is to be congratulated on his report for 1926. The health of the children of Shrewsbury may be considered very satisfactory. The percentage of children found to require treatment on routine medical inspection was very low (9·2 per cent.). He attributes this to four possible causes: (1) environment (absence of large quantities of industrial smoke, open spaces and playing fields, the equable climate); (2) absence of poverty or unemployment as found in some industrial towns; (3) the cumulative effect of child welfare work in the borough; and (4) the provision made by the education committee for the health and welfare of the children. He gives an interesting hypothetical case illustrating the coördination between the various agencies responsible for the health and welfare of children from birth to adolescence. With regard to vaccination, it is pointed out that of 2854 children, admitted to school during the last seven years, 1199, or 42 per cent., were unvaccinated; in other words, only just over half of the present elementary school population in Shrewsbury is protected—and even then only partially protected—against small-pox. Dr. Symons discusses the difficulties in administrative control of infectious outbreaks in the school. A pamphlet is reproduced giving directions for the treatment of impetigo in the home.

Extracts from the replies of the head teachers on the subject of cod-liver oil and malt in the schools are illuminating. Dr. Symons states that the cost of supplying the cod-liver oil to 179 children was £30. Eighty-nine per cent. of the children much increased in weight. The treatment he regards as preventive, and the small amount of malt and oil may just turn the balance in many cases by warding off tuberculosis or other infections. He goes on to say that it is more economical to spend £30 a year on 179 children in this way than to wait until they become casualties. It would cost the same sum of money to maintain one child as a tuberculous cripple at the orthopædic hospital for 12 weeks only.

There are no special schools for mentally defective children in the borough, and it has to be borne in mind that the state is difficult to detect. Each individual case has to be examined in a thorough manner, mentally and physically, and this examination cannot be done properly in less than one hour. This responsibility must, however, be faced, for experience has shown that it is necessary at the earliest possible moment to separate the three classes: (1) those who can be taught in an elementary school; (2) those who can be taught only in a special school; (3) those unfit for any school.

City of Carlisle.

Dr. Joseph Beard, M.O.H. and S.M.O., notes that there were 95 less routine inspections than in the previous year, the decrease being in the later age-groups. The number of routine inspections was larger among entrants, showing the continuing effect of the increase in the annual birth-rate which followed demobilisation. The percentage of defects is considerably lower, 6·37 less than in 1925 and 12·7 less than in 1924. The decrease is most marked in non-tuberculous lung disease, in tuberculous conditions of all sorts, and in anæmia and malnutrition—conditions that are specially important for the outlook in later life. Cleanliness is also more usual, t apparent paradox of a greater number of exclusio for verminous conditions is explained by the great number of inspections and especially the surpri visits paid by nurses for this purpose. The rearrang ment of the surprise visits is expected to lead to marked improvement in cleanliness in the futu Dr. Beard gives a list of the schools with the numb of unclean children in each; such lists may have good influence by stimulating a competitive effo to be the cleanest school in the town. Dental work satisfactorily carried on, the fillings of permane teeth being three and a half times as many as t extractions, and as Dr. Beard says, that experien shows that any conservative work that has been do proves to be of a lasting nature, and that the gene cleanliness of the teeth of all groups is well maintaine It is certainly to be regretted that the percentage refusals of dental treatment (37·2) is so high, becau the children in this group are at an age when t six-year molars can be satisfactorily treated; is surprising since the number of parents attendi medical inspections is good (54·17) and increasing.

There are as yet no special schools in Carlisle, n any adequate orthopædic scheme, though for delica children there are the Newtown delicate classes a 66 children were sent to the Sillath Convalesce Institution through the medium of the Council Social Service, which also provides a voluntary clin for the treatment of cripples. It is evident that the is need for a properly equipped open-air school, complete orthopædic scheme, and schools for t physically and mentally defective.

INFECTIOUS DISEASE IN ENGLAND AN WALES DURING THE WEEK ENDED AUGUST 27TH.

Notifications.—The following cases of infectio disease were notified during the week: Small-po 166 (last week 103); scarlet fever, 1354; diphtheri 705; enteric fever, 103; pneumonia, 384; puerper fever, 41; puerperal pyrexia, 115; cerebro-spin fever, 7; acute poliomyelitis, 29; acute poli encephalitis, 4; encephalitis lethargica, 23; co tinued fever, 2; dysentery, 7; and ophthalm neonatorum, 115. No case of cholera, plague, typhus fever was notified during the week.

Deaths.—In the aggregate of great towns, includi London, there were no deaths from small-pox enteric fever, 16 (1) from measles, 4 (2) from scarl fever, 8 (3) from whooping-cough, 15 (2) from dip theria, 72 (8) from diarrhœa and enteritis und 2 years of age, and 20 (5) from influenza. The figur in parentheses are those for London itself.

THE Lister Centenary Exhibition at the Wellcon Historical Medical Museum, 54A, Wigmore-street, will closed on Oct. 1st. Since its inception in April the exhi tion has been inspected by a large number of visitors fr all parts of the world.

A CONFERENCE ON LIBRARIES.—Some 200 organis tions will be represented at the Fourth Conference of t Association of Special Libraries and Information Bureau which is to meet at Trinity College, Cambridge, fro Sept. 23rd–26th. After a reception by Sir J. J. Thoms (Master of Trinity College), Sir Geoffrey Butler, M.P., w deliver the presidential address. Among others who w read papers are Sir Henry Lyons, Mr. A. E. Overton, a Sir Richard Gregory. The subjects to be discussed inclu the recent report of the Public Libraries Committe coöperation between libraries, and book selection in scien and technology. Sectional meetings will be held on inform tion and statistics in commerce and industry, on pate classification, and on information bureaux. The conferen is open to all interested, and particulars may be had fro the secretary of the Association at 38, Bloomsbury-squa London, W.C. As we have already announced, t Association is publishing in the autumn a directory of sourc of specialised information, edited by Mr. G. F. Barwick, la Keeper of Printed Books at the British Museum.

Correspondence.

"Audi alteram partem."

EXAMINERS AND EXAMINEES.

To the Editor of THE LANCET.

SIR,—In connexion with the article by Dr. Alan oncrieff in the Modern Technique in Treatment ries on Diseases Associated with Examinations, hich appeared in your Students' Number ugust 27th), there is a proposal which I brought fore the College of Physicians of Edinburgh over years ago which would, I think, if adopted, prevent e occurrence of such disorders, at any rate to a very nsiderable extent. Let me briefly explain my eaning.

At a professional examination the factor which believe acts most powerfully in inducing mental rturbation in the good student is what may be med "the unknown." The natural remedy would erefore be to conduct the examinations, at any rate e oral and clinical parts of them, practically "in e open." In this way the prospective candidate, ving had frequent opportunities of witnessing the aminations and of familiarising himself with their quirements, character and standard, would know ll in his own mind when he was fit to pass and would, the proper time, appear before his examiners with ich less diffidence and anxiety.

Of course, in the adoption of such publicity some xra thought, consideration, and care would have be exercised by the medical authorities as regards e practical arrangements and carrying out of the aminations. But, as we all must recognise, publicity a thing that is always worth obtaining from the dico-sociological point of view, and one must not get that publicity as regards professional examina-ns other than medical is no new thing. Moreover, ointed out at the time that in a large medical ool where there are many students to be taught l many candidates to be examined, publicity as ards examinations would present another advan-e. This was that the hours and days spent in the mining of students instead of being, as at present, oss to the teaching work, would become to it a st helpful and valuable adjunct.

I am, Sir, yours faithfully,

dinburgh, Sept. 1st, 1927. ALEX. JAMES, M.D.

To the Editor of THE LANCET.

IR,—Dr. Alan Moncrieff's judicious article in THE CET for August 27th on the treatment of disorders ciated with examinations must assuredly have kened memories, many unhappy, in the minds very medical man and woman reading it. He deals fly with the examinee. May I, in a few lines, with the examiner? Though I was never oughed" in a medical examination, and though e than a score of years have passed since I ified, my impressions of certain incidents at the geons' Hall in London and at Cambridge remain leasantly vivid. An examiner is sometimes a leman; who could have any but kindly memories hat model of courtesy and consideration, Sir ord Allbutt? But could he be called a typical miner? One of the worst types is the youngster, a short and brilliant career, intolerant of less d mortals. Many other types, all objectionable ne way or another, could be described. We ex-examinees know them so well that I need describe them. How can they be eliminated heir malice assuaged? What consideration is resent paid by those who appoint examiners to tesy, patience, and a sense of justice as necessary ifications in an examiner? What may be a less gibe at other times may be a cruel taunt the object thereof is passing through a real s in his life, nerves stretched to breaking point by months of over-work. About two generations ago a medical examiner had "savaged" a batch of examinees so effectively that a deputation waited on the university authorities and secured his dismissal. But for one such case, how many are there in which the cavilling, jeering examiner is free to continue to cavil and jeer? I have already indicated the possibility of one remedy. Another is to foster an opinion in favour of courtesy and fairness in examiners. It is with this object that I am now trespassing on your space. Yet another is to make every *viva voce* examination public, to allow anyone who wishes it to be present. A few years ago I witnessed a public *viva voce* at the University in Oslo and was impressed by its fairness. There may be yet other remedies; I hope so, for I am not sure that I have shown how to bell effectively that most catty of cats, a bad-tempered examiner.

I am, Sir, yours faithfully,

CLAUDE LILLINGSTON, M.D. Cantab.

League of Red Cross Societies, Paris, Sept. 2nd, 1927.

ANTISPECIFIC CYTOLYSINS AND MALIGNANT DISEASE: A HYPOTHESIS.

To the Editor of THE LANCET.

SIR,—Some two years ago [1] I argued as a probable hypothesis that the body in its reaction against malignant disease produces cytolysins which are nearly or quite as toxic to itself as to the tumour, and that malignancy is due not to the tumour but to these cytolysins alone. The weakest point in the argument appeared to be the doubtful existence of these antispecific cytolysins, for which, so far as I then knew, no direct evidence had ever been obtained. That much evidence now exists seems clear from Miss Kohn-Speyer's paper in THE LANCET of August 20th, and I would urge again that this hypothesis of malignant disease should at least be considered. It appears to explain very simply all the peculiar phenomena of malignancy, the fretting of tissues at the tumour's edge, the metastases, the cachexia; if this be so, why should we involve ourselves in needless difficulties by supposing a further virus in the tumour itself? If this hypothesis can be accepted it will greatly simplify our view of malignant disease, and may have an important bearing on its treatment. For if malignancy is not in the tumour, but wholly in the body's reaction to it, then evidently any tumour will cease to be malignant, if the body can be induced to ignore it.

I am, Sir, yours faithfully,

Plymouth, Sept. 1st, 1927. C. R. CROWTHER, M.D.

THE TRIAD OF SALERNO.

To the Editor of THE LANCET.

SIR,—Sir Thomas Horder, in his MacAlister lecture on Diet and Dietists, reported in THE LANCET of July 16th (p. 103), alluded to "the old adage, ascribed to Swift, which states that the three best doctors are 'Dr. Diet, Dr. Quiet, and Dr. Merry-Man.'" J. J. Walsh, in his booklet on "Medieval Medicine" (1920, p. 55, n.), states that the opening lines of the 1607 edition of the English translation of the *Regimen sanitatis salernitanum* "deserves to be noted because they are the origin of an expression that has been frequently quoted since," going on to italicise the following couplet:—

Use three physitians still—first Dr. Quiet,
Next Dr. Merry-man, and third Dr. Dyet,

which is apparently a translation of an original

Si tibi deficiant medici, medici tibi fiant
Haec tria, mens hilaris, requies, moderata diæta.

This drives one back to the "offscourings of the Bodleian" that are said to have formed the substance, the flesh clothing the anatomical structure, of Robert

[1] Brit. Med. Jour., Jan. 23rd, 1926.

Burton's "Anatomy of Melancholy," which originally appeared in 1621. Sure enough it is to be found in Part II. (2.6.4.):—

"The merrier heart, the longer life; *a merry heart is the life of the flesh*, Prov. 14. 30. *Gladness prolongs his days*, Ecclus. 30. 22. and this is one of the three *Salernitan* Doctors, Dr *Merryman*, Dr *Diet*, Dr *Quiet*, which cures all diseases—*Mens hilaris, requies, moderata dieta.*"

These three doctors, however, with Englished names, are to be found earlier than 1607; whether the idea from which they took rise is traceable to Salerno (as is probably the case) or not. In Dr. J. C. Bucknill's useful, but somewhat superficial booklet on the "Medical Knowledge of Shakespeare" (1860, pp. 26–27), there is a quotation from Bullein's "New Boke of Phisicke" of 1559, in the form of what Bucknill calls "the following good story," in which, to our surprise, the triad is to be found:—

"Once I fel into a great sicknes, and hitherto I am skant recovered of it, the surfite was so great; but counsail was geuen me, that I should not stay myselfe upon the opinion of any one Physition, but rather upon three: then said I: to retain three at once, requireth great charge, for those men to whome lives be committed ought liberal rewardes to be geuen. Then sayde my frend, they are good gentlemen, and no great takers. What be theyr names, said I: He answered saying: The fyrste was called Doctor Diet, the second, Doctor Quiet, the third, Doctor Merryman."

A new turn is given to the phraseology of the saying by Longfellow (1807–82) in his "Poetic Aphorisms," which were based on the seventeenth century *Sinngedichte* of Friedrich von Logau:—

"Joy and Temperance and Repose
Slam the door on the doctor's nose."

This is equally Salernitan with the others, although in this, its latest dress, it will be seen that *tibi deficiant medici* in a way that was not exactly intended by the compiler of the *Regimen sanitatis* of Salerno.

I am, Sir, yours faithfully,

Manchester, August 23rd, 1927. W. J. RUTHERFURD.

TEACHING OF SWIMMING.

To the Editor of THE LANCET.

SIR,—I have been in communication with the local education authority of Wandsworth concerning this subject, and I think it would be advisable to comment on the subject before the summer passes and interest in swimming is diminished.

Fourteen years ago the Wandsworth Education Committee taught children of both sexes under 7 years of age swimming. The teaching commenced in the month of May; the baths were emptied and cleaned, and then filled with tepid water; the girls and boys went on alternate days, three times a week each. The girls went in batches of 34 at a time; they were taught to swim on their faces, on their backs, and also the American side stroke. So all that is asked now is that the Wandsworth education authority would do now what they did 14 years ago. They do not do so; the L.C.C. have sought the assistance of the London Schools Swimming Association, and, acting on their advice, they refuse to consider the teaching of children under 7 swimming, because they feel sure that the Minister of Education would prohibit it. But they have not consulted him in any way; he has had no opportunity of expressing an opinion. There are three sets of people who ought to have their say in the teaching of swimming to these young children. First, the parents, who should be consulted as to whether they wish their children to be taught at so young an age, or whether they wish it to be postponed till they are 11 years of age or more (vide THE LANCET, July 17th, 1926, p. 160); secondly, the school education authority, who take upon themselves to decide the matter for everybody; and thirdly, the *health* authorities, who are ignored and they at least ought to be considered by THE LANCET—they probably do not know what is going on.

I am, Sir, yours faithfully,

WALTER EDMUNDS.

Carlton-road, Putney, S.W., Sept. 2nd, 1927.

ASTHMA AND ARTHRITIS IN ALTERNATIO

To the Editor of THE LANCET.

SIR,—I agree with Dr. Stone that it is not altogetl unexpected that asthma should disappear during attack of arthritis, but it is, I think, somewl surprising that the patient should be free from ac arthritis during an asthmatic phase. The interest point about the case I quoted, and also about Long's case, was that the patient never had b complaints together, and was never free from eitl one or the other. Incidentally, her asthma did disappear during an attack of influenza.

I am, Sir, yours faithfully,

Dublin, Sept. 2nd, 1927. SYLVIA B. WIGODER, M.D

The Services.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are notified: Surg. Capt. C Baxter to *President*, for three months' post-graduate cou Surg. Comdrs. W. C. Carson to *Vivid*, for R.N. Barrac H. H. Babington to *Repulse*, and J. S. Austin to *Mala* for R.N. Hospl., Bermuda. Surg. Lt.-Comdrs. A. G. Bee *Maidstone*, amended orders; R. P. Ninnis, to *Vivid*, R.N. Barracks cancelled; and C. N. Ratcliffe to *Pembi* for R.N. Hospl., Chatham, temp., supy., amended ord Surg. Lts. A. de B. Joyce to *Maidstone* and to *Vivid*, R.M. Infirmary, Plymouth, amended orders; G. W. Ga to *Comus*, temp.

Surg. Lt.-Comdr. A. C. Anderson to rank of Surg. Com Lt. (retd.) B. T. Brewster to rank of Lt.-Comdr. (ret

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub-Lt. A. T. G. Thomas to be Surg. Lt.

Proby. Surg. Sub-Lt. D. C. Livingstone to *Furious*, 28 days' training.

The Medical Department of the Admiralty announce t Surgeon Lieut.-Commander Allan Watt McRorie, M.B., R. has been awarded Sir Gilbert Blane's Gold Medal, he hav obtained the highest aggregate marks at the examinati held in 1927 for promotion to the rank of Surg Commander.

ROYAL ARMY MEDICAL CORPS.

Capt. H. N. Stafford to be Maj.

The undermentioned Capts. to be Majs.: J. F. Bourke S. J. L. Lindeman.

The undermentioned are secd. for duty with the Su Def. Force: Capt. R. J. Rosie, Capt. E. G. Dalziel, Lt. J. D. Corner.

Surg. Capt. Philip Graeme Bentlif, from the R. Jersey M L.I., to be Lt.-on prob., and relinquishes the rank of Surg. Ca

Lt. P. G. Bentlif is secd. under the provisions of Art 2 Royal Warrant for Pay and Promotion, 1926.

Temp. Lt. W. D. Dyson relinquishes his commn.

Capt. Sorab Curshedji Contractor to be Maj.

T. Capt. Baldeo Singh Gill relinquishes his commn.

DEATHS IN THE SERVICES.

Surgeon Lieut.-Commander John Stephen McGrath, wh death occurred on June 29th, was born in 1893 at Ross de Santa Fé, Argentine Republic. He went to Ireland 10 years of age and entered Rockwell College, afterwa taking up medical studies at University College, Cork. entered the Navy as a surgeon probationer in June, 19 and served in the North Sea until 1917, when he gradua M.B., B.Ch., in the National University of Ireland. Dur the latter part of the war he served in the Eastern Medi ranean and he was on board *Glorious* at the surrender of German fleet in November, 1918. After the war he ser on the China Station and in the Mediterranean, be invalided from the Navy with the rank of surgeon lie commander. Last winter he took a course of study at Coombe Hospital, Dublin, but he was in poor health and a severe attack of influenza in the spring. He died at Glasne Dublin, at the age of 34, leaving a widow and a daughte

Obituary.

WILLIAM JOSEPH TYSON, M.D. DURH., F.R.C.P. LOND., F.R.C.S. ENG.

Folkestone loses a distinguished citizen by the eath of Dr. W. J. Tyson, which occurred on Sept. 5th. r. Tyson was notable both as medical practitioner ıd as man of affairs, and during the latter part of his fe devoted much time to public work as chairman of ıe Royal Victoria Hospital and in other capacities. Born at Folkestone in 1851, he was the son of Dr. 'illiam Taylor Tyson, and was educated at Queen's ollege, Taunton. He qualified in 1874 from Guy's ospital, where he became house surgeon and obstetric sident. Two years later he took the Fellowship the Royal College of Surgeons of England and t up in practice at Folkestone. In 1881 he graduated doctor of medicine in the University of Durham ıd in 1889 became a Member of the Royal College Physicians of London. At this time he was acting medical officer to the Folkestone Hospital and was riting on a variety of subjects, reading numerous ıpers before the Clinical and Pathological Societies London, in whose *Proceedings* they may be found. the course of the next few years these papers tracted attention to his talents, and in 1901, during s third term of office as President of the Folkestone edical Society, Dr. Tyson was elected a Fellow of the oyal College of Physicians. Throughout his pro- ssional life he continued his contributions to medical urnals and they revealed an alert and observant ind. He also wrote two small books based on edical notes from his own practice. Dr. Tyson's rly connexion with the Folkestone Hospital was ntinued as physician and he resigned this office ly recently after nearly 50 years of constant service. e became chairman of the institution on the death Sir Stephen Penfold. Some 20 years ago he was pointed a justice of the peace for Kent and at the ne of his death was chairman of the Elham Division unty Magistrates. For many years, also, he presented Christchurch, Folkestone, in the Church ational Assembly, where his clear views and easy eech were much appreciated. During the war he ted as examiner and lecturer on Government rvice.

Dr. Tyson married the daughter of Mr. J. H. du oulay, of Sandgate. His widow survives him with ree daughters.

ARTHUR PERCY ALLAN, M.D. LOND.

Dr. Percy Allan, who died at his home at South oydon on Sept. 2nd, was for 25 years one of the edical representatives on the standing committee convocation of the University of London, and the same period was medical secretary of the niversity of London Graduates' Association. He s born at Chislehurst in 1868, the son of Mr. John lan, and was educated privately and at Birkbeck llege. Graduating as M.B. Lond. in 1894, he came clinical assistant, and later house physician, Guy's Hospital. After finishing his house appoint- nts he settled down to make a practice in Croydon, d succeeded in doing so under considerable diffi- ties. "He was an admirable practitioner and a nny fighter," writes Dr. Graham Little, "and those o knew the medical school of Guy's in the early ieties will hear of his death with a very especial ng of sorrow. Throughout his life he retained the vish freshness and ardour—and the engaging lisp— ich endeared him to his fellow students." Dr. an was honorary surgeon to the St. John mbulance Association, and during the late war good service as medical officer in charge of one of auxiliary military hospitals, receiving the Médaille Roi Albert. He wrote on many medical subjects, ides having wide interests outside his profession. was a profound student of Rabelais and had devoted much time to mythology and symbolism. A great deal of his leisure, however, was given to the University of London and he took an active part in the elections to the Senate, possessing a real flair for electioneering.

Dr. Allan married the daughter of Mr. Richard Clark, and she survives him.

WILLIAM THOMAS EVANS, M.B., C.M. EDIN.

Dr. W. T. Evans, who died on Sept. 3rd at Bromley, Kent, was the son of the late Mr. Charles Evans, F.R.C.S., and was born at Bakewell in Derbyshire in 1853. He was educated at Derby School and in 1870 proceeded to the University of Edinburgh, where he graduated in medicine five years later. After holding the post of resident house surgeon at the Edinburgh Royal Infirmary he settled in practice in West London and took up a number of public appointments, being medical officer of the West District, Paddington, and of the St. John's Training School for Girls, Westbourne Park. On retirement from practice in 1920 he went to live at Bickley in Kent. His death, which followed a fortnight's illness, occurred from heart failure. Dr. Evans married a daughter of the late Mr. Thomas Hughes, and his widow survives him with three children, one of whom is Major D. G. Evans, R.A.M.C.

FRANK PERCY ELLIOTT, M.B., C.M. ABERD.

AFTER some 35 years of practice at Walthamstow, Dr. F. P. Elliott died suddenly on August 30th at the age of 57. He came of an old Sussex family and was born at Jamaica, where his father and uncle were engaged in sugar-planting. Graduating in medicine at the University of Aberdeen in 1894, he accepted a locum tenency at Walthamstow and thus began his connexion with the district. He became attached to numerous institutions in the neighbourhood and notably to the Walthamstow Public Dispensary, of which he was senior medical officer. He was especially interested in infant and child welfare, and in 1915 established a child welfare centre at Walthamstow with beds for serious cases. A limited instalment was provided for the treatment of rickets by light, but the facilities then available did not fully satisfy him, and early this spring he acquired a large house and garden for the centre. The house contained a large installation for electrical and ultra-violet light treatment, and Dr. Elliott took it over only eight days before he died, expressing the hope that his medical friends would avail themselves fully of the opportunities afforded for treating their patients at the centre. Dr. C. W. Chapman, to whom we are indebted for some of these particulars, writes of his old friend as follows: "The outstanding feature of Dr. Elliott's character was the obliteration of self-interest in unstinting service to others. He typified the highest ideal of the family doctor and gentleman, and his relations with his professional colleagues were of the highest order." Dr. Elliott's hobby was his rock garden, and he had a remarkable knowledge of flowers in general.

NEW AUXILIARY HOSPITAL FOR GREENOCK.—It is proposed to build an auxiliary hospital for Greenock in the Kip Valley at a cost of £60,000. Provision is made for 38 beds and the building will be equipped with an up-to-date operating theatre.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Dr. James Wheatley, county medical officer of health for Shropshire, has been elected President of this Society for 1927–28, and will deliver his presidential address at the house of the Society on Friday, Oct. 21st, at 5 P.M.—The annual dinner will be held at the Piccadilly Hotel, London, W., on Thursday, Nov. 17th, when the Minister of Health and the President of the Board of Education will be the principal guests.—The Neech Prize for the best paper read before a branch or group of the Society has been awarded for last session to Dr. E. H. R. Harries, medical superintendent of the Birmingham City Hospitals, for his paper on the Serum Treatment of Scarlet Fever.

MEDICAL CERTIFICATION OF INCAPACITY OF INSURED PERSONS FOR WORK.

A CIRCULAR (Memo. 307/I.C.) for the information of insurance practitioners has just been issued on behalf of the Ministry of Health for England and Wales and the Scottish Board of Health. It has been prepared with a view to assisting insurance practitioners in the discharge of their duties under the Medical Certification Rules. The first part of the memorandum consists of a discussion on the general meaning of the term "incapable of work," in the hope that a concise statement of certain main points on which there has been general agreement will be welcomed by practitioners. The statement does not purport to be a legal definition by the Ministry, but is a summary of views generally accepted by those responsible. In the first place it has not been held to be necessary for the purpose of establishing a title to sickness or disablement benefit, that the insured person should be found to be incapable of work in the sense of being completely unable to carry out the physical or mental processes which constitute "work." An insured person has been regarded as "incapable of work" through some specific disease or bodily or mental disablement when he is in such a condition that an attempt to work would be seriously prejudicial to his health. If it seems likely that he will soon be able to resume his former work, it is unreasonable to expect him to undertake other work in the meantime, and he may be properly regarded as incapable of work in the interim. But there has been some misunderstanding by practitioners as to their duties in cases where there is no reasonable prospect of the patient again being able to resume his ordinary occupation. Here a different criterion from that of fitness for that occupation must be applied, and the patient should not be certified as incapable of work unless in the practitioner's opinion he is physically unable to perform any other suitable kind of remunerative work, whether at once or after a short course of training. It is then the business of the approved society concerned to determine (subject to the member's right of appeal) for what period the payment of benefit should reasonably continue. A note as to pregnancy concludes this part of the memorandum; the State is not regarded here as necessarily rendering the insured person "incapable of work." While in some persons incapacity for work may be partly or wholly due to pregnancy, others will not be incapacitated.

The second part of the circular is more definitely concerned with the rules and regulations of medical certification. Clear and precise instructions as to the forms and dating of certificates and as to the details of procedure are set out. The proper use of first, second, and subsequent certificates are concisely explained, also the regulations governing voluntary certificates, advice as to additional benefits, exempt persons, persons receiving hospital treatment, and persons over 70 years of age. The caution given in a previous memorandum against the ante-dating or post-dating of certificates is repeated, and practitioners are asked to resist any importunity from insured patients or others in this matter. Among other points dealt with are certificates on death of patient, certificates in cases where benefit is not claimed, and certificates in respect of patients referred to the regional medical officer. It is noteworthy that the responsibility of the regional medical staff is confined to that of *advising* societies and practitioners respectively, and the practitioner is not precluded from giving certificates of incapacity to a person who has been stated by the regional medical officer to be capable of work, if the practitioner is of opinion that the patient is in fact incapable of work.

Some helpful explanation is given of the practitioner's duties in those cases where the certificate issued by him is intentionally vague because a precise statement might prejudice the health of the patient or inflict upon him unwarrantable injury. Here a special form of certificate must, in addition, be sent to the approve society and a detailed statement of the circumstanc to the regional medical officer. The difficulties of ear diagnosis are realised, but practitioners are warne that the approved societies cannot be expected accept without question certificates containing gener terms (such as "fever" or "debility") unless they fin that these terms are used by the practitioners onl when they have not yet been able to make a mo precise diagnosis. It is suggested that at least suc additional information as "debility with anæmia, "debility with high temperature," or "debility wit dyspepsia" might be given even at an early stag A final caution against laxity in certification and the custody of books of certificates concludes th memorandum.

Medical News.

WEST LONDON HOSPITAL.—At 4 P.M. on Monda Oct. 3rd, Sir Henry Simson, Dean of the hospital, will ope the winter session with a paper on Post-graduate Educatio in Obstetrics. There will be continuous instruction unt Christmas in general medicine and surgery and in all speci departments.

IRISH FREE STATE MEDICAL COUNCIL.—The Roy College of Physicians of Ireland last week nominated D T.G. Moorhead as its representative on the Free State Medic Council. Dr. Moorhead is Regius Professor of Physics Dublin University and one of the physicians to Sir Patric Dun's Hospital.

POISONING BY TINNED TOMATOES.—At an inque held at Sheffield on August 24th it was stated that a who family had fallen ill after eating tinned tomatoes, and o of the children, a boy aged 5, had died two days later a result. Post-mortem examination was said to have show that death was due to solder in the tin having been dissolve by the acid juice of the fruit.

CHELSEA CLINICAL SOCIETY.—The annual dinne will be held at the Café Royal, 68, Regent-street, W., o Tuesday, Oct. 25th, at 7.30 P.M. (Reception at 7 o'clock The following subjects will be discussed at meetings of th Society during the session: Focal Sepsis (Nov. 15th Orthopædics in General Practice (Dec. 13th), What Prescribe and Why (Feb. 21st), Modern Aspects of Dentist (March 20th), the Future of Gas Warfare (April 17th), an the Clinical Value of Biochemical Methods (May 15th All these meetings will be preceded by a dinner at th Hotel Rembrandt at 7.30 P.M., and will begin at 8.3 There will also be a clinical meeting at St. George's Hospit on Jan. 17th at 8.30 P.M.

FELLOWSHIP OF MEDICINE AND POST-GRADUAT MEDICAL ASSOCIATION.—On Sept. 19th the Westminst Hospital will start a fortnight's course in medicine, surger and the specialties. There will be lectures, demonstration and operations from 10.30 A.M. to 5.30 P.M. (fee £3 3s. On the same date the Royal National Orthopædic Hospit will start a two weeks' course consisting of lecture-demonstra tions from 11.30 A.M., operations at 9.30 A.M. or 10 A.M., an out-patient work each afternoon (fee £2 2s.). Durin October courses will be given in antenatal work at th Royal Free Hospital (limited to ten) on Fridays at 5 P.M (fee £1 1s.); in cardiology at the National Hospital fo Diseases of the Heart, from 10 A.M. to 4 P.M. (limited to 2 fee £7 7s.); in diseases of children at the Victoria Hospit and Paddington Green Hospital, all day (fee £3 3s.); i diseases of the throat, nose and ear at the Centra London Throat, Nose and Ear Hospital, all day. This cours is divided into two parts, clinical and operative, which ma be taken separately or together, the numbers for th operative class being limited (fee £5 5s. for clinical cours and £7 7s. for operative class). There will also be courses i electrotherapy at the Royal Free Hospital on Wednesday at 5.15 P.M. (fee £1 1s.); in gynæcology at the Chelsea Hospit for Women, mornings and/or afternoons (fee £5 5s.); i tropical medicine at the London School of Hygiene an Tropical Medicine, on Tuesdays and Thursdays, at 2 P.M (fee £2 2s.), and in neurology at the National Hospita Queen-square, for two months. A series of Fellowshi lectures entitled Practical Hints in Medicine, Surgery, an the Allied Specialties will be opened by Sir Humphr Rolleston on Monday, Oct. 17th, at 5 P.M. There will als be series of weekly clinical demonstrations in medicin surgery, and ophthalmology open to members of the medic profession without fee. Copies of all syllabuses and of th general course programme are obtainable from the Secretar of the Fellowship at 1, Wimpole-street, London, W. 1.

Appointments.

ORY, NORMAN A., F.R.C.S., has been appointed Ear, Nose, and Throat Surgeon, Royal Northern Hospital, London.

urgeons under the Factory and Workshop Acts: CHEESE, F. W., for the Ludlow District, Salop; HASKINS, N. H. H., for the Deal District, Kent; MARTIN, E. W. D., for the Tunbridge Wells District, Kent; OAKEY, T. J., for the Darlaston District, Stafford; ROBINSON, F. W., for the Leiston District, Suffolk; ROGER, H., for the Towcester District, Northampton; SWAINE, R. O., for the Bognor District, Sussex; TAYLOR, W. A., for the Aylesbury District, Buckingham; THOMAS, W. S. R., for the Warlingham District, Surrey.

ng Urban District Council.—Part-time M.O.H. £350.
erhampton and Midland Counties Eye Infirmary.—H.S. £200.

Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Exmouth (Devonshire).

Births, Marriages, and Deaths.

BIRTHS.

ANGUS.—On August 30th, the wife of Alan Angus, M.D. Durh., Oxford-terrace, Gateshead, of a son.
DOHERTY.—On August 31st, at Welbeck-street, London, the wife of W. D. Doherty, M.A., M.Ch., F.R.C.S., of a son.
EDE.—On August 29th, at Strangeways, Calne, Wilts, the wife of Cuthbert Ede, M.D. Camb., of a son.
LITHERLAND.—On August 28th, at Milton Lodge, Wigan, to Doris Litherland, M.R.C.S. Eng., L.R.C.P. Lond. (née Knowles), the wife of Henry Litherland, L.S.A. Lond.—a son.
RAMMELL.—On August 31st, the wife of Dr. John Rammell, of St. Albans, of a daughter.
SLATER.—At Stagsden Nursing Home, Bournemouth, on the 14th August, to the wife of J. McDonald Slater, M.B., F.R.C.S. Edin., a daughter.
STEVENS.—On August 28th, at Redholme, Thame, the wife of A. Langley B. Stevens, M.B., B.Ch. Oxon., of a son.
WEBSTER.—On August 7th, at Baroda, India, the wife of Captain W. J. Webster, M.B., Ch.B. Aberd., of a daughter.

MARRIAGES.

MCCANN—PAPIER.—On Sept. 4th, at Bombay, Captain J. G. McCann, I.M.S., M.R.C.S. Eng., L.R.C.P. Lond., to Miss Gabriel Papier.
SOMMERVILLE—RILEY.—On Sept. 1st, at St. Anne's Church, Kew, Surrey, Angus Christopher Sommerville, M.R.C.S. Eng., L.R.C.P. Lond., of Otford, Kent, to Joan Riley, Kew-gardens, Surrey.
STARKEY—MCLEMAN.—On August 30th, at St. Columba's, Church of Scotland, Pont-street, S.W., Richard Scott Starkey, M.A., M.B. Camb., of Amersham, Bucks, to Barbara Alice Mary, elder daughter of the Rev. John and Mrs. McLeman, of the U.F. Manse, Methil, Fife.

DEATHS.

ACTON.—On Sept. 1st, at Wrentham, Charles James Acton, M.R.C.S., L.R.C.P. Lond., D.P.H., of Wangford, Suffolk, aged 65 years.
ADAMS.—On August 28th, at Kenninghall, Norfolk, William David Adams, M.A., M.B., C.M. Edin.
ALLAN.—On Sept. 2nd, at Crogdene, Croham-road, S. Croydon, Arthur Percy Allan, M.D., B.S. Lond., aged 59 years.
BARNES.—On Sept. 2nd, at St. Edmund's, Pontac, Jersey, Edgar George Barnes, O.B.E., M.D. Lond., L.S.A., M.R.C.S. Eng., in his 79th year.
ELLIOTT.—On August 20th, at 113, Grove-road, Walthamstow, Frank Percy Elliott, M.B., C.M. Aberd., aged 57.
GIBBES.—On August 25th, 1927, Cuthbert Chapman Gibbes, M.D., M.R.C.P. Lond., 89, Harley-street, aged 76.
MACVICKER.—On August 30th, at a nursing home, Clifton, Charles George MacVicker, M.B., B.Ch., B.A.O.R.U.I.
NEILD.—On August 29th, at Shaugh Cottage, Hartfield, near Tunbridge Wells, Edith Neild, M.B. Lond., L.R.C.P., L.R.C.S. Edin., aged 53 years.
TYSON.—On Sept. 5th, at Folkestone, William Joseph Tyson, M.D. Durh., F.R.C.P. Lond., F.R.C.S. Eng., Chairman Royal Victoria Hospital, Folkestone.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee 49 cases were considered and £776 10*s.* 8*d.* voted to 43 applicants. The following is a summary of some of the cases relieved:—

Widow, aged 34, of M.B. Glasg. who died in May last. Left with two children, boy 10, girl 9. Would willingly support herself and children, but employment is difficult to obtain owing to not being trained. Temporary grant of £3 given.

L.R.C.S. Edin., aged 72. Married, no children. Through continual ill-health applicant and his wife have had to live upon their savings which are now reduced to £81. Only income Epsom Pension £40 and old age pension £26. Rent and rates £26. Voted £40 in quarterly payments.

M.B. Glasg., aged 66. Carries on a pharmacy which was purchased with his late wife's money. On the death of his wife all her money went to her relations. The local secretary of the Fund reports that applicant's memory is so bad that he is not capable of following his profession or business. Rent £40 inclusive. Special grant of £5 and £40 in 12 monthly instalments voted.

Daughter, aged 70, of M.R.C.S. who died in 1883. Two sisters and a brother live together. One sister an annuitant of the Fund. They share expenses. Applicant asked for help towards a holiday. £5 voted.

Widow, aged 72, of M.R.C.S. Eng. who died in 1902. Brother-in-law provided for applicant and her family until 1921. Eldest a cripple from 7 years of age. Daughter aged 43 earning £2 a week. Advised to take a boarding-house, but not being able to get tenants is unable to meet expenses and asks for a grant towards rates. Voted £18.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

Notes, Comments, and Abstracts.

PATHOLOGICAL AND BACTERIOLOGICAL LABORATORY ASSISTANTS' ASSOCIATION CONFERENCE.

THE second conference of the Pathological and Bacteriological Laboratory Assistants' Association was held in the Department of Pathology, University of Cambridge, from August 22nd to 26th. In the absence of Prof. H. R. Dean (the President), Mr. W. A. Mitchell (the Vice-President) introduced the Rev. G. A. Weekes (Vice-Chancellor of Cambridge University), who declared the conference open. He said that he had heard of no other association of the kind existing in any of the other great scientific departments. The members of the Association wanted to increase scientific knowledge, to compare methods and techniques, and to give one another results of their own independent investigations. They were not intending to be merely useful and competent officials. It was significant of the high standard of tradition in the work of the scientific departments, in laboratories, that people were prepared to spend part of their holiday in a conference of this kind. He recalled the words of Pasteur, that in the realm of research luck only favoured the minds that were prepared. Discoveries were not made by people through luck alone. The "esprit préparé" could be gained not only by listening to lectures and discussions, but by the more informal and social meetings, when workers met and compared experiencee, and went away regarding everyone in that domain as a brother and comrade.

The Vice-President delivered a lecture on Cambridge, illustrated by lantern slides, and then presented the Junior Greenfield Prize and Medal to Mr. Edward B. Brain (Birmingham) for a number of colour drawings of pathological subjects.

The following lectures and papers were delivered: Standard Dietary for Rabbits and Guinea-pigs, E. Pleasance (Cambridge); The Manufacture of Small-pox Vaccine as Carried Out in the Laboratories of the Shanghai Municipal Council, A. E. P. Grimmo (Shanghai); Antagonism and Symbiosis of Bacteria, J. J. Ritchie (Edinburgh); The Development of Parasitology, Prof. G. H. Nuttall, F.R.S.; Cinema Films of Scientific Interest, G. Harper (Birmingham); Virulence Test in the Identification of *B. Diphtheriæ*, S. Denyer (London); Diversions of an Overseas Laboratory Assistant, A. Saunders (South Georgia); Rare Fæcal Organisms which Simulate Pathogens, J. McLean (London); The Preparation of Plague Vaccine, F. Leeson (Gold Coast); Laboratory Work in a Spa Hospital, S. Linfoot (Harrogate); The Biuret Reaction, E. C. Haddon (Uganda); Difficulties Encountered in the Differentiation of Paratyphosus A, B, and C, S. J. Denyer (London); The Mounting of Frail Museum Specimens on Wax Plates, H. Gooding (Manchester); Tissue Culture Technique, V. C. Northfield (Cambridge); A visit was made to the Institute of Animal Pathology and a demonstration of the method of producing antitoxin was given by A. G. Thompson. Veterinary specimens were shown by E. F. Hughes.

An exhibition of laboratory work and apparatus was on view during the conference; tissue culture exhibits showed stained preparations, a pulsating heart culture, and dark ground preparations of mitosis in living cells. The exhibits were as follows: The Cultivation of Protozoa, W. Cooper and W. J. Muggleton (London); Specimens of Malignant Pustule, F. J. Drury (Northampton); Examples of Artistic Portrayal of Medical and Surgical Conditions, D. Kidd (Liverpool); Photomicrographs, G. R. Armstrong (Cardiff); Micro-filaria found in Human Blood, C. E. Berry (London); Micro-chemical Apparatus, C. W. Ashton (Manchester); Sections of Central Nervous System, H. Gooding (Manchester); The Evolution of the Method of Mounting Specimens in Gelatine according to the late Prof. Delépine's Methods, F. Simons (Manchester); Diagrams of Morbid Histological Conditions, R. Muir (Edinburgh); Chromogenic Organisms, Photogenic Organisms, Sections illustrating Common Pathological Conditions, Bacteriophage, Living Wandering Cells, Pathological Specimens, members of the Department of Pathology, Cambridge.

The Sims Woodhead Medal was presented to Prof. Lorrain-Smith, F.R.S., the Association's first President, in recognition of his great services to the Association since its formation in 1912. Mr. Richard Muir accepted the medal on behalf of Prof. Lorrain-Smith, who was unexpectedly prevented from being present. The conference dinner was held in the dining hall of Trinity Hall on Thursday evening; 104 members and guests were present. The principal guests were the Vice-Chancellor and Prof. G. H. Nuttall.

The attendance at the conference was fully representative of this imperial organisation, including members from as far afield as the Gold Coast, South Georgia, Shanghai, as well as from all parts of the British Isles.

POST-GRADUATE STUDIES IN MANCHESTER.

THE chief feature of post-graduate work in Manchest during the coming academic year will be a new series courses given by the University and the hospitals attach to it. While the successful hospital lectures given in the la few years have been arranged chiefly for medical men in t full swing of practice, the University courses are design for those who can give up consecutive periods for intensi study. They form the foundation of a post-graduate scho which it is hoped to develop in the near future. T immediate courses are: an intensive one in medicine a surgery, Sept. 12th–30th, and in obstetrics and gynæcolo from Oct. 1st–8th. From January to March part-tir courses on tuberculosis and diseases of the ear, nose a throat will be arranged for the benefit of medical officers health, school medical officers, and those engaged in materni and child welfare work. Application should be made to t Dean of the Medical School, from whom information may obtained.

The Royal Infirmary offers an attractive programme lectures on Tuesday and Friday afternoons. In addition those given by the acting members of the honorary sta Dr. E. M. Brockbank will lecture on some points in t medical aspect of the industrial history of Lancashi Mr. Spalding, of the Deaf and Dumb Schools, will demonstra advances in the training of the deaf child, Dr. Veitch Cla will speak on immunisation against diphtheria and scar fever, Dr. W. M. Roberts will explain his recent work gastric analysis, and Dr. A. D. Macdonald will describe t physiology of shock. The Lloyd Robert Lecture for t year will be given at St. Mary's Hospital, Whitworth-stre on Nov. 1st by Dr. Hector Charles Cameron on the Ch in General Practice: A Study both of Temperament a Disease.

DIAGNOSIS IN EXCELSIS.

A CORRESPONDENT in New Zealand has sent us a copy of t "Medical Pickwick," vouching for the truth of an episo which is humorously illustrated. To the doctor's inqui of the patient as to what he had eaten for dinner, t patient said that he could not remember, but aske "Can't you tell by looking at my index-finger?"

MADD DOGS.

To the Editor of THE LANCET.

SIR,—In the interesting note on Madd Dogs in THE LANC of August 13th the writer is of opinion that the fact "poore Pompey" being "sent to be made" suggests th Pompey was an inanimate object. Is it not more probab that Pompey was a sporting dog—probably a pointer—a that he was sent to be "made" or trained in the same sen that a hunter or steeplechaser is "made"?

I am, Sir, yours faithfully,

Clevedon, August 17th, 1927. R. L. WASON.

THE CAMPAIGN AGAINST MALARIA.

A SENTENCE in our article last week (p. 522) might sugge that the League of Nations Malaria Commission have confidence in "indirect" measures against malaria. therefore wish to point out that the Commission attach ve great importance to one of them—namely, "bonification" which acts by raising the agricultural productivity of area and hence improving the economic and educatio status of the inhabitants. We should have made it cle that in all their journeys the Commission found only t regions where *antilarval* measures had been carried o on a considerable scale with definitely successful resul This finding made them lay all the more stress on indire measures which reduce the incidence of malaria witho necessarily destroying the anopheline mosquito.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY LIMITED.

(FOUNDED 1892)

Registered Office: VICTORY HOUSE, LEICESTER SQUARE, W.C.2.

Telegrams: "MEDICAVERO, WESTRAND, LONDON." *Telephone:* REGENT 0611.

President: Sir JOHN ROSE BRADFORD, K.C.M.G., C.B., C.B.E., M.D., P.R.C.P., F.R.S.
Treasurer and Chairman of Council: C. M. FEGEN, M.R.C.S., L.R.C.P., D.P.H.
Trustees for the Reserve Fund:
Rt. Hon. LORD DAWSON, G.C.V.O., K.C.B., M.D., F.R.C.P. Sir ANTHONY A. BOWLBY, Bart., K.C.B., K.C.M.G., K.C.V.O., F.R.C.S. Sir HARRY BALDWIN, C.V.O., M.R.C.S., L.D.S.

The Society was founded for the following purposes: To protect, support, and safeguard the character and interests of legally qualified Medical and Dental Practitioners; to advise and assist Members of the Society in matters affecting their professional character and interests; and to indemnify them in regard to actions, etc., undertaken on their behalf.

SUBSCRIPTIONS. There is an Entrance Fee of 10s., and an Annual Subscription of £1.

The Invested Funds of the Society exceed £38,100. The Society is fully insured to an unlimited extent against all adverse costs and damages which may be awarded against Members in any action which the Society undertakes on their behalf.

Forms of application for Membership and full particulars may be obtained from the Secretaries at the above address.

BAILLIÈRE, TINDALL & COX'S

Announcements.

READY NEXT WEEK. Twelfth Edition. Thoroughly Revised.

ROSE & CARLESS' SURGERY

→ "The best text-book of Surgery in English."—*Lancet.* ←

Demy 8vo. Pp. xii + 1,554.

With 19 Coloured Plates, an X-ray Supplement containing 78 Photographs and 639 other Illustrations, and an appendix of Military Surgery.

Price **30s.** Postage: Inland, 1s.; abroad, 1s. 8d.

ANATOMICAL, PHYLOGENETICAL AND CLINICAL STUDIES ON THE CENTRAL NERVOUS SYSTEM

By B. BROUWER, Professor of Clinical Neurology, University of Amsterdam.

¶ Professor B. Brouwer has long held a distinguished position among Dutch neurologists and he has been engaged for many years in special investigation in this field at the University of Amsterdam and elsewhere. In the present volume Professor Brouwer presents the results of his investigations.

Demy 8vo. Pp. x + 67. With 16 Illustrations. Price **11s. 6d**, postage 6d.

JUST PUBLISHED. Second Edition, with the inclusion of 36 Coloured Plates.

MACKENNA'S DISEASES OF THE SKIN

By ROBERT W. MACKENNA, M.D., B.Ch.(Edin.), Lecturer in Dermatology, University of Liverpool, etc.

¶ "*A book which is a credit to British Dermatology.*"—BRITISH JOURNAL OF DERMATOLOGY.

Royal 8vo. Pp. xii + 450. With 36 Coloured Plates, 143 Illustrations, and many Formulæ. Price **25s.**, postage 1s.

JUST PUBLISHED. Crown 8vo. Pp. 240, with 7 Plates. Price **13s. 6d.**, postage 9d.

EVOLUTION OF PREVENTIVE MEDICINE

By Sir ARTHUR NEWSHOLME, formerly Principal Medical Officer, Local Government Board of England.

The object of this volume is to present a summary of the chief figures and major triumphs of preventive medicine, and, in the process, makes clear the principles upon which the science is founded and on which it must continue to win new laurels.

SECOND EDITION. **HANDBOOK OF GYNÆCOLOGY**

By BETHEL SOLOMONS, B.A., M.D. (Univ. Dub.), F.R.C.P.I. Master of Rotunda Hospital.

"*For the purpose for which it is intended the book could scarcely be surpassed, but it ought to appeal to an even wider circle. No better introduction to medical work could well be placed in the hands of a student, and we venture to think that there are few medical men who might not read it with profit.*"—Extract from Review in THE LANCET.

Demy 8vo. Pp. xiv+304, with 2 coloured plates and 217 illustrations. Price **12s.**, postage 9d.

JUST PUBLISHED.

HYPOTENSION

By ALFRED FRIEDLANDER

Professor of Medicine, College of Medicine, University of Cincinnati.

¶ It presents the first attempt to collect and critically to analyse the literature on Low Blood Pressure.

Royal 8vo. Pp. xvi + 193. Price **11s. 6d.**, postage 6d.

JUST PUBLISHED.

ACTINOTHERAPY

FOR GENERAL PRACTITIONERS

By H. G. FALKNER

L.R.C.S.I., L.R.C.P.I., L.M. ROT. DUB., O.B.E

Demy 8vo. Pp. x + 152, with 36 plates and illustrations.

Price **7s. 6d.**, postage 6d.

BAILLIÈRE, TINDALL & COX, 7 & 8, Henrietta St., Covent Garden, LONDON, W.C.2.

An Address
ON
MENTAL UNITY AND MENTAL DISSOCIATION.*

BY WILLIAM BROWN, M.D. OXF., D.Sc.,
M.R.C.P. LOND.,
WILDE READER IN MENTAL PHILOSOPHY IN THE UNIVERSITY OF OXFORD; PSYCHOTHERAPIST TO KING'S COLLEGE HOSPITAL, LONDON; HON. CONSULTING PSYCHOLOGIST, BETHLEM ROYAL HOSPITAL, LONDON.

IT is important to realise that the problem of mental unity and dissociation is in direct relationship to the problem of unity and dissociation in the physical and physiological spheres. The point of view from which we should first approach it is that of biology. The general tendency throughout evolution seems to be towards the building up of totalities or wholes, in which each separate activity takes place in relation to the whole. The general conception is not that of a purely mechanistic scheme in which we begin with particles of matter and consider how they interact with one another to produce a more and more complex system, but one in which there is a guiding unity from the beginning. We may indeed, as metaphysicians, assume that there is a guiding unity of the entire universe. But short of such an ultimate generalisation we find that observation itself reveals this tendency towards a progressive development and multiplication of unities, in relation to which individual activities occur.

1. BIOLOGY AND PSYCHOLOGY.

In one sense, biology may be regarded as the most fundamental of the sciences, and even the simpler physical and chemical activities occur as parts of systems, which may be likened to organisms in having an environment to which their reactions are adjusted. This biological point of view needs for its completion the psychological point of view, which is not something distinct from the biological, but a continuation of it. Psychology is a completion of biology as a science, and gives further meaning to it. The unity of the organism becomes more intelligible when we think of it as a mental, and in part a conscious unity. It is a unity in plurality. Physically, the organism is a unity of parts in spatial relation to one another; psychologically, it is a system of mental tendencies in relation to one another. What we find physically is a reaction to an environment in the form of reflex action, simple or conditioned. Psychologically, response to external stimulation is the satisfaction of conation, and, at higher levels, satisfaction of desire, &c. Biologically, it is the struggle for existence, with all that this involves. Psychologically, it is a conscious striving first of all for something that the individual does not know—towards a goal which he gradually realises, gradually learns to understand as he achieves it or fails to achieve it. However helpful the biological concepts of tropisms and conditioned reflexes may be as explanatory factors, the psychological point of view throws further light upon the situation. The ultimate factor that has to be considered is something that is *purposive*—a general striving—which factor has to be assumed in order that the theory of conditioned reflexes will work.

2. NORMAL AND ABNORMAL DISSOCIATION.

Unity of mind, then, is something which develops. In its general form it is there from the beginning, but it only exists in relation to a multiplicity. There is a one-and-many relationship from the beginning. Moreover, the individual himself is, to some extent, an abstraction. He belongs to a species. He has a history, and his history is, in part, the history of the entire species. The history of the species is part of the history of organic evolution, and the history of organic evolution is part of the history of the Universe—if, indeed, we may think of the Universe itself as having a history. But within the individual experience there are partial activities that may struggle with one another just as individual members of a species may compete with one another, and in this nisus or striving towards more complete unity and greater complexity and more adequate adaptation to environment, the process of dissociation shows itself as essential and normal. Right from the beginning we must realise that dissociation is just as normal and necessary as association. The mind as it grows must be able to reject, and also must be able to segregate one activity from another. Different activities must be insulated from one another to a great extent within the organism, just as in an electrical machine there must be insulation of the wires. This insulation is what is meant by normal dissociation or disjunction. And from the pathological point of view there can be disturbance in both respects—disturbance of association and disturbance of dissociation. Experiences may become associated in such a way as to blur the clearness of vision of the individual as regards appearances and values, just as, more obviously, dissociation may go beyond its proper function and tend to destroy the unity or totality towards which normal striving is directed.

3. THE NATURE OF MENTAL ASSOCIATION.

The earlier associationist doctrine of psychology was unsatisfactory because, among other things, it failed to distinguish between the process of experiencing or the act of experiencing, and the content or object of experience; and its aim seems to have been to describe the mind as a sort of mosaic of contents of experience joined up to one another according to the laws of association by contiguity and similarity. But association is primarily between the acts of experience. These acts of experience are differentiations of the fundamental striving—that which Spinoza called the *conatus in suo esse perseverare*, "the striving to persist in one's own being." This striving has an object. There is always an object—the environmental changes which the individual has to face—and corresponding with the complexity of the environment there is a complexity developing within this general striving, forming a complex system of conations. This conation involves the two other well-known aspects of cognition or awareness, and of feeling-tone. Associationist psychology erred in failing to allow due weight to the conative side, and in attempting to range the different kinds of feeling on a level with the different kinds of objective experience. But even according to the associationist scheme, dissociation or disjunction was necessary for a complete explanation of normal mental activity. Side by side with the principles of association by contiguity and similarity, there was the principle of dissociation by varying concomitance. Only by such a principle could the important processes of discrimination, comparison and abstraction be brought within the circle of associationist doctrine. The general scheme of explanation was wrong, in that it dealt with contents of experience when it should have been dealing with acts of experience; and the general scheme of mental activity which we put in the place of this associationist scheme is that of systems of mental tendencies included within, and in subordination to, a wider system—tendencies towards knowledge and action, and involving feeling. One such system of explanation is that in terms of instinctive-emotional dispositions organised within sentiments, with the sentiments in their turn subordinated to one all-inclusive sentiment or master-interest. A sentiment is an organisation of emotional dispositions centred about the idea of some object. What are organised are not the presentations or representations, not the contents of experience

* Presidential Address to the Section of Psychology of the British Association at the Leeds Meeting. The paper was supplemented by descriptions of cases illustrating mental dissociation.

primarily, but the processes or acts of experience. The tendencies of experience, and the activity and organisation of these tendencies, bring with them an organisation of the objects; and so our memories, which are retained and which are used for the retention of past experiences, fall into systems because the acts of experience corresponding to those memories fall into systems. And from that point of view we see that the dissociations of memory—the gaps in the memory continuum, known as amnesias—find their true significance in the segregation of corresponding acts of experience.

The question then arises, if we reject the associationist scheme according to which the mind is built up of presentations and representations cohering together in systems, are we to regard the unity of the mind as an aggregation of mental activities and tendencies? Are we to put in place of our mosaic of mental contents a collection or a colony of mental tendencies? The reply is "No," because we do not have these mental tendencies separate from one another—just coming together and cohering, just as we do not have the mental contents coming together and cohering. Both subjectively and objectively, we must assume at the beginning a generalised striving and mental tendency, with a generalised objective—e.g., "the great big buzzing confusion" of which William James speaks as the world of the new-born babe—a continuum of sensation and movement on one side, and a continuum of mental striving on the other. The general mental striving which we assume at the beginning becomes gradually differentiated in relation to the needs of the organism, and the demands made upon the organism by its environment—a differentiation superimposed upon the differentiations accumulating in the history of the race, and handed on from generation to generation in the form of instinctive endowment and inherited aptitudes. The individual inherits not only separate instincts, but also the tendency towards an organisation of those instincts. He inherits the beginnings of sentiments, as well as instincts. He is already a one-and-many unity, with his mind a plurality of part-tendencies and processes, and his task in life is to carry that organisation to a higher stage. The demands made upon him by his environment bring with them movements in two directions—in the direction of greater unity and greater organisation, and also of greater complexity—a greater degree of differentiation and discrimination. Discrimination is necessary because he has not only to accept, but also to neglect or reject, and this neglecting or rejecting involves dissociation, just as acceptance involves association.

4. THEORIES OF PATHOLOGICAL DISSOCIATION.

As regards dissociation in pathological cases, the writers of the last generation thought of this in terms of associationist psychology, and in the doctrine of Prof. Pierre Janet one finds that standpoint still apparent. In his description of cases of hysteria and multiple personality, he implies a general background of explanation, according to which personality may be regarded as a synthesis of mental presentations some of which can be split off from the main mass. This view is similar to the colonial view of personality which we find in the writings of Ribot. But if we remind ourselves of the fact that experience involves an act of experiencing, we see that the situation is rather different. The power of recall is an essential aspect of conscious memory. On the other hand, unconscious memories are unconscious or latent mental activities directed towards past events. They are not passive, but involve a certain amount of mental energy. And so we pass from Pierre Janet's theory to the theory of Prof. Sigmund Freud, and we find that the dissociation which is taken as a fact in Janet's theory is explained in Freud's theory in terms of mental conflict and repression. These memories become inaccessible to the individual because the mental tendencies corresponding to them are in conflict with other tendencies of the individual and incompatible with his more fundamental interests. So they are extruded by an active process of repression—they are barred from consciousness.

That process of repression and extrusion, though pathological in these cases, need not be necessarily so. We must not look upon extrusion itself as essentially pathological. It is because we have restricted the word dissociation so much to the pathological side that we find it so incomprehensible to us. It is because we have thought too much in terms of mental unity that cases of multiple personality seem to be inexplicable. Actually the most normal mind is a multiplicity. We are all many selves. We have to face the world from many different angles. We have many different interests. Interests in the most normal mind may conflict and be incompatible with one another. And it is a condition of mental health that such conflict can be resolved by elimination or by a higher synthesis. What makes the dissociation of multiple personality pathological is that the elimination is not complete—that dissociation in normal mental activity is a successful rejection and that dissociation in a pathological case is unsuccessful—is an incomplete and therefore an unsuccessful rejection. A tendency that is pathologically repressed is, as it were, rejected and accepted at the same time—rejected by clear consciousness but still clung to by the mind.

It is misleading to look upon the problem of mental dissociation and multiple personality as something standing by itself, as if we understood mental unity and were perplexed by the appearance of multiplicity. Multiplicity is an aspect of the normal mind, just as much as unity is, and unity needs explaining just as much as multiplicity does. Those two problems must be solved together, and kept in relation to one another all through.

5. MULTIPLE PERSONALITY.

Many of the classical cases of multiple personality are fully explained along these lines. They are cases of alternating personality with reciprocal amnesia, as it is called, in which each personality is unable to recall the experiences of the other. The two individuals A and B alternate with one another. A has his own system of memories and, when he disappears and makes way for B, B has his system of memories distinct from the memories of A. We may explain this in terms of two general systems of interests which are mutually incompatible and in conflict with one another. As a rule, one part of the personality is more fundamental—i.e., more stable, than the other. But difficulty arises in cases where one personality is shut up within its own memories and experiences while the other personality has access to those memories as well as to its own. A may have his system of memories but be quite ignorant of B except from indirect evidence, whereas B not only has a special set of memories, but also has direct knowledge of A's memories, thoughts and feelings. This is a difficult problem which needs to be faced. We find an analogous, though not identical, situation in most cases of deep hypnosis. When a patient passes into the hypnotic state, he may remain fully aware of his waking consciousness, and may have free access to the memories of his waking self. But on awaking he does not, as a rule, remember his hypnotic experiences. The relation is a one-sided one. The hypnotic personality is acquainted with the waking personality, and all its memories, but the waking personality is not acquainted with the hypnotic personality. The range of the hypnotic personality is wider than the range of the waking personality. This similarity between one-sided multiple personality and the hypnotic personality is significant, when we remember that such cases have been investigated by the hypnotic method. Pierre Janet, Morton Prince and others used the hypnotic method in studying cases of multiple personality, and the criticism has been made against them that in doing so they were manufacturing personalities—that the personalities were artefacts produced by the method. Everyone

ecognises that these investigators are psychologists f exceptional ability and circumspection and honesty f purpose, thoroughly trained and alive to the ossibilities and difficulties of their method. We annot dismiss their observations as false observaons, or as misunderstandings on their part. But e must nevertheless allow for the influence of the rocess of hypnosis in the result, and as contrasted ith that earlier period of investigation—the hypnotic eriod in psycho-pathology—we find that, now that ypnosis is seldom used and has been replaced by eep analysis, cases of multiple personality are not n record. The psycho-analysts to-day seem to have o such cases to report. Moreover, if we contrast ne very large number of cases of severe nervous isturbance caused by the late war with the absence cases of multiple personality there, we may become ill more impressed by the argument that it was the ersistent use of the hypnotic method that was ainly responsible for the complexity of most of the rlier cases reported.[1]

The movement of thought is always towards stem and unity. Thought abhors hard-and-fast stinctions. Thought is baffled by cases of multiple ersonality because they are so different from the dinary cases of everyday life. If we can build bridge between one group of cases and the other, en we may feel that we are likely to have not only more satisfying but a true explanation of the uation.

We must therefore approach the question of ssociation from the normal side—as manifested in relatively normal mind. No mind is completely rmal, since no mind completely solves its problems m day to day, and it is the failure to solve mental oblems which is one of the general causes of the mptoms of psycho-neurosis and mental disease. ssociation and multiple personality are not to be ntrasted with association and mental unity. athological dissociation should be contrasted with e dissociationist processes of the normal mind. should be regarded as a failure of the normal ocess of dissociation.

AUTOGNOSIS INCREASES MENTAL INTEGRATION, HYPNOTISM MAY DIMINISH IT.

The unity of the normal mind, although it is there m the beginning, is a striving towards a more and re complete association; it constitutes an urge a greater and greater degree of completeness of stematisation and inclusiveness, but it is never ally complete. In the most normal mind there is a lling away from complete unity. There is in the tivity of this unitary mind not only a normal process disjunction or dissociation, but also a certain degree abnormal dissociation. In cases of multiple rsonality this abnormal dissociation has become so nounced as to be apparent to the whole world. ne process of deep analysis or psycho-analysis ls to reveal cases of thorough-going multiplicity, d the reason is that the process itself is a process unification. As the individual is being analysed, e failures of adaptation in his past life are cleared , so that his mind is enabled to work more and re normally. Analysis is not a good term for this ocess. It is more than analysis, it is a process of f-revelation or *autognosis*. The individual learns know himself better, and in the process of analysis ere is actual development of the mind going on. ere is a development in the direction of the normal d the unitary. Any dissociation that is encouraged the method is a normal dissociation, not an normal dissociation. It is only another expression the same truth when we say that repressions are ercome in the process of analysis, because repress-ns are pathological dissociations—dissociations at are not complete and not thorough going.

In contrast with this process of autognosis, the process of hypnotic investigation carries with it a tendency to abnormal dissociation. A person who is easily hypnotised is a person who is already, to some extent, dissociated; in hypnotising him we take a wedge, as it were, and drive it into his mind and split him up still more. No wonder the results give us an appearance of dissociation; but it would be very dangerous for us to take these results at their face value and draw inferences from them as to the structure of the normal mind, or even of the mind of the person we have been experimenting with. This general line of criticism seems valid as against such a theory as that of Prof. W. McDougall in the last chapter of his "Outline of Abnormal Psychology," in which he works out a theory of the Self as a system of monads which form a hierarchy, in which there is one dominant monad, the conscious self, and a whole number of subsidiary monads that are, in a normal mind, adequately subordinated to the chief monad and are in relation to the chief monad through telepathy[2]; but in a case of multiple personality one of these subsidiary monads may break loose and become insubordinate. This is an ingenious theory, and it may be true, but in the present state of our knowledge it would seem to be a case of explaining *obscurum per obscurius*. Telepathy may be a fact, but it is something about whose *conditions* we know next to nothing, and therefore not very suitable to take as a fundamental factor in an explanation of the working of the mind.

The mind can act at different levels on different occasions and under different circumstances. In many of the classical cases of multiple personality, the subsidiary personalities represent a regression to more juvenile forms of behaviour and of ethical valuation. This is clearly apparent in "Sally Beauchamp" of the Miss Beauchamp case, and in the "B" personality of the "B.C.A." case (Morton Prince). Such manifestations are not accurately described as "split-off" personalities. Indeed, any spatial metaphor is inappropriate. In other cases the tendency to dramatisation, natural to the human mind, may play an important part. Mutually incompatible ideas of character may be simultaneously or alternately aimed at, and identifications in early life, based on love and admiration for relatives, &c., may introduce incompatibilities which reveal themselves under circumstances of stress in later years as the grounds of pathological dissociation.

7. AB-REACTION AS A METHOD OF OVERCOMING MENTAL DISSOCIATION.

As regards the problem of the *removal* of pathological mental dissociation in hysterical patients, much was learnt from the wide range of cases dealt with during the war. While treating shell-shock cases in the field in France, I found that a large proportion of the cases showed a more or less extensive amnesia for events that had occurred immediately after the shell explosion. These patients were easily hypnotised, and under light hypnosis the lost memories could be immediately restored. But I soon discovered that if I recalled at the same time the terrifying emotion that had originally belonged to these experiences, there was a tendency for the accompanying hysterical symptoms—deafness, mutism, tremors, paralysis, contractures, &c.—to disappear spontaneously, without the necessity of giving explicit suggestions to this end. The more complete I made the working-off of the emotion, or the "ab-reaction," to use Breuer's original term, the more complete was the recovery. In cases seen by me previously in England, I had also restored lost memories by light hypnosis, but had not produced intense emotional revival and had not seen collateral symptoms disappear. But again, towards the end of the war, I was seeing more chronic cases in Scotland, and then found that amnesias of longer standing could be cleared up with accompanying ab-reaction of the

[1] Cases of extensive amnesia, fugues, &c., were numerous ring the war; but the first aim of the army doctors in the ttle areas was to remove these amnesias and reassociate the tients as quickly as possible, so that the latter might be either urned to the line or sent down to the base with the minimum delay.

[2] Unlike the monads of Leibniz, which "have no windows," and are in a relation of pre-established harmony.

emotion of fear; and that with the ab-reaction there was observable that tendency for the collateral symptoms to disappear at the same time, such as I had observed so frequently in France.

These are observed facts, and I endeavoured to show in a paper some years ago[3] that they could be explained in terms of a theory of reassociation. The amnesic patients fresh from the trenches showed a two-fold dissociation, namely (1) a dissociation of the memory of events immediately following upon the shell explosion from memories of earlier and later parts of the patient's life; and (2) a dissociation of these memories, as mere intellectual awareness, from the accompanying emotional reactions of fear—tremors, sweating, mutism, paralysis, &c.—which are of a physiological nature. The physical reaction of fear, thus dissociated from its psychical counterpart, had become relatively permanent instead of being transitory. The patient no longer felt the emotion of fear—at least, of just that fear which the shell explosion had aroused—but did show its physical manifestations in the form of hysterical symptoms. By re-arousing the whole of the lost experience in all its emotional vividness I overcame *both* dissociations. The physical manifestations became linked up with their psychical counterpart, and this in its turn was linked up with earlier and later memories of the patient's life. In this way the mind was completely resynthesised, and the physical symptoms came once more under the sway of the entire mind (the complete personality) and could disappear.

In addition to ab-reaction, I advocate the thorough thinking out of the whole psychological situation by the patient, so that he may be brought eventually to understand himself adequately. This is the process of autognosis, or self-knowledge. The patient is encouraged to obtain as objective a view of his entire mental condition as is possible.

8. Ab-reaction and Transference.

C. G. Jung[4] has explained the beneficial effects of ab-reaction in terms of "transference." By transference is meant the emotional rapport (conscious and unconscious) which springs up between patient and physician, and which enables the patient to live again, in the course of an analysis, through earlier experiences of his life in relation to the physician, and thus become freed from their harmful effects. The following case illustrates how ab-reaction can bring benefit without the factor of transference coming in. It is a case of a man of considerable education, who had for some years suffered from obsessive fear, the origin of which he could not fathom. He would wake up in the morning with this fear weighing upon his mind. After reading about the method of ab-reaction, as used in treating shell-shock patients, he thought that he would try to cure himself by a similar method. He endeavoured to recall earlier and earlier memories of his past life, using the method of concentration—to all intents and purposes producing a light degree of self-hypnosis. At length he seemed to get this memory: it was half a memory, half a waking vision. He seemed to be in a sort of native compound in India. He experienced intense heat, such heat as he never remembered experiencing in his life before, and seemed to see a black kid lying on the ground with its throat cut and blood pouring out of the wound. He felt intense terror as he went through this experience. This terror grew and grew "like a bubble." It got bigger and bigger and at last burst, and all at once the fear began to subside again and eventually disappeared, and he remained free of it afterwards. As far as one could make out—he came and told me of it afterwards; I had not treated him at the time—he had cured himself of the fear by bringing up this memory. He could not be certain that the memory was a real memory, but thought that it probably was, because he had lived in India up to the age of two, when he left for England and had not returned since. It was thus probable that it was a real experience; if not so in all its details, the central kernel of the experience was probably real, and its recall was effective in curing him. It will be noticed that he did not ab-react this experience in relation to another person. He was not in a doctor's consulting-room, telling the doctor what he could remember. He was by himself. He had not even gone to a doctor beforehand, so that it could not be described as a transference towards the doctor in the latter's absence. He had not applied to any doctor for treatment at that time. He came on to me afterwards, simply to talk the matter out still further, and to learn whether he had been working on the right lines, and how he should proceed in order to ensure that the fearsome experience should not return. An example like this is a refutation of the view that the only beneficial effect of ab-reaction is the transference. Transference is indeed often the chief factor of cure, and in many ab-reaction cases transference is an additional factor. But an example like this shows that ab-reaction by itself has therapeutic value, in contradiction to Jung's view.[5]

Ab-reaction of repressed emotion sweeps away the repression, and so frees energy which had been previously needed to hold the repressed memories apart from the rest of the mind and away from clear consciousness. This freed energy is thus put once more at the general disposal of the personality. The previous "fixation" of this repressing energy and its deviation from the common fund of energy of the personality probably explains, to some extent, the feeling of fatigue that generally accompanies a psycho-neurosis.

9. Personality and Survival of Bodily Death.

The unitary personality, as an organisation of mental activities and mental powers, is not static but dynamic, and is in process of development throughout life. Although it carries with it, as a physical correlate, a unitary working of the brain and of other parts of the body, this does not necessarily involve complete dependence upon the latter for its continued existence. The question of personal survival of bodily death is one which can be intelligibly and scientifically put, and which is in theory answerable along the lines of scientific observation and inference. The investigations carried out by the Society for Psychical Research during the past 50 years are of this nature, and the Society's results and provisional hypotheses can rightly claim a place in modern psychological science. Nevertheless, if due allowance is made for the possible working of such factors as conscious or sub-conscious fraud, telepathy between the living, and chance coincidence, the scientific evidence for personal survival of bodily death is not very strong.

For more convincing reasons (apart from the pronouncements of revealed religion) in support of this belief we still have to turn to philosophy, and in modern philosophical theories of *value* we find arguments that are far from negligible.[6]

ST. MARY'S HOSPITAL.—The annual report of St. Mary's Hospital records that the year has been disastrous from the point of view of the ordinary income. The total income was £55,824 and the excess of income over expenditure was £8567. An appeal was launched during the year for £50,000 to provide two operating theatres and 46 additional beds for accidents and sudden emergencies. Towards this extension £32,000 has so far been received. Street accidents treated at the hospital numbered 107 per day.

LUMINAL-SODIUM IN THE TREATMENT OF EPILEPSY.

BY J. TYLOR FOX, M.D. CAMB.,
MEDICAL SUPERINTENDENT, LINGFIELD COLONY FOR EPILEPTICS, SURREY.

THIS paper records the results obtained over a eriod of five or six years by the administration of minal-sodium in an epileptic colony. The population f the colony consists of children and young people, nd no doubt represents a less hopeful type of the isease than would be met with in ordinary practice. t includes those who by reason of severe or frequent ts, of defective intelligence, or of abnormal behaviour re unfit for ordinary home or school life, though, roadly speaking, it does not include any who should ome under the provisions of the Mental Deficiency r Lunacy Acts. In most cases the disease has been nder treatment for some years before admission to ie colony, so that those who respond readily to romides have already been eliminated. As a general ile, no drugs are given to a patient on entering ie colony. A certain number of patients react vourably and promptly to colony life by an arrest striking diminution of their fits. This may be ie to more suitable diet, fresh air, or a more regular id simple life, but it is more likely the result of ie removal from an environment involving emotional rain or from objects or events which were linked, y association, with some unpleasant emotion. ailing such a favourable response, after a few months, ixed bromides are, as a rule, prescribed in doses creasing up to a maximum of 20 or 30 gr. a day, cording to the age of the patient. Luminal has nerally been given when other therepeutic measures ive failed, or when the number of fits has been creasing, or the patient has been obviously going wnhill. It will be clear, therefore, that the results t out below have been obtained with rather tractable and unfavourable cases of epilepsy.

The dosage of luminal-sodium has varied from 1–3 gr., ven once in the 24 hours, either in the morning evening. The great majority of the patients have id 2 gr. a day. The size of the dose has not been ken into account in recording the results of eatment. It is pretty clear that larger doses are ther, but not much, more effective than smaller; it, as tolerance so frequently sets in and the ission of the drug may be such a serious matter, ses of 3 gr. or more should not be lightly prescribed.

must be remembered that luminal-sodium is nerally said to be rather less effective than luminal elf in the treatment of epilepsy.

Effect of Luminal-sodium on the Incidence of Fits.

In this investigation only those cases were included here the fit figures, observed on the colony, for the months prior to the luminal administration are ailable, and where the duration of luminal adminis- ation was at least six months. Any alteration of sage during administration is ignored. In this and bsequent investigations, benefit or decrease of s means that the monthly average was reduced by e-third or more, harm or increase of fits means at the monthly average was increased by one-third more. The figures for 167 cases are available, and e results show that 50 (or 30 per cent.) show benefit at is likely to be permanent, 51 (or 31 per cent.) er showing benefit for a period of more than three nths apparently became tolerant to the drug, in (or 33 per cent.) the incidence of fits was unaltered only decreased temporarily for a period of less an three months, while in the remaining 10 cases 6 per cent.) there was an increase of fits.

Out of the 50 cases showing benefit, 9 (or 5 per cent. the whole) have had their fits completely arrested such long periods—in no case less than two years— at one can anticipate with some confidence that ey will not recur.

Successful Cases.

A study of the features of the complaint in those nine cases fails to disclose much that might lead us to define a type particularly likely to respond to this form of treatment. The principal facts about them are as follows:—

CASE 1.—Male. Father had fainting fits as a boy. Two sisters have had fits. Epilepsy began at 18 months. No cause assigned. Type of fits, major attacks at the rate of seven a month, periods of automatism lasting 10 seconds at the rate of five a month. Intelligence quotient estimated about 0·70. Luminal treatment began at the age of 22. Immediate complete cessation of all attacks. Two years later patient left colony and is now, after six years of treatment, still free from any kind of fits and earning his living at poultry farming.

CASE 2.—Male. Mother's father attempted suicide. Epilepsy began at 8 years. No cause assigned. Type of fits, majors one every two or three months, very frequent very slight momentary attacks. Intelligence quotient 1·07. Luminal treatment began at the age of 12. After the first two months total cessation of all attacks, and now, two years later, is still free.

CASE 3.—Male. Mother's father committed suicide. Epilepsy began at 2 years, but there was a five-year period of freedom from fits up to 7 years. No cause assigned. Type of fits, petit mal lasting a few seconds in which he occasionally fell right down. Intelligence quotient 0·90. Luminal treatment began at age of 10. All fits immediately ceased, and now, nearly two years later, have not recurred. All-round mental improvement with luminal.

CASE 4.—Female. Family history nil. Epilepsy began at 6 months. No cause assigned. Type of fits, major attacks more than three a month. Intelligence quotient 0·82. Luminal treatment began at age of 12. Immediate cessation of all fits which, three years later, have not recurred. More irritable during first few months of luminal treatment.

CASE 5.—Male. Mother's uncle epileptic and insane. Epilepsy began at 8 years of age. No cause assigned. Had major attacks at the rate of three in two months. Intelligence quotient 0·90. Luminal treatment started at age of 12. Immediate and complete cessation of all attacks, and patient is now, five years later, still free from fits and earning his living in London.

CASE 6.—Male. Illegitimate. Aunt had epilepsy. Epilepsy began in second year and followed immediately on a fall from a high chair on to his head. Fits very irregularly, mostly of major type, and in the year before luminal was started averaging rather more than two a month. Intelligence quotient 0·79. Luminal started at age of 15, with resultant complete cessation of attacks, but marked increase of patient's irritability. Now, two and a half years later, patient has left the colony and is earning his living at gardening. The fits have not recurred.

CASE 7.—Male. Mother's brother infantile paralysis. Father's sister imbecile. Fits started at 4 years. No cause assigned. Type of fits, majors at rate of 12 a month, similar attacks with loss of consciousness but incomplete convulsions ten a month. Intelligence quotient 0·77. Luminal started at age of 8. Fits stopped at once and patient is still, three years later, free from them. The rapid mental deterioration which was in evidence before the fits stopped was arrested, but there is some reason to think that it is now slowly asserting itself again. Probably the boy will always require institutional care.

CASE 8.—Male. A brother died of convulsions. Epilepsy began at 4 years. No cause assigned. Type of fits, very frequent screaming attacks lasting a few seconds and occasional majors. Intelligence quotient 0·58. Luminal started at age of 21. Some mental imbalance is evidenced by short catatonic attacks during first few weeks of luminal administration. Apart from these, complete cessation of fits has continued for over five years. The patient's mental defect has, however, necessitated his retention in an institution.

CASE 9.—Male. Mother died of fits and tumour on the brain. A brother died of convulsions. Fits began at 13 years of age, said to have followed a fall. Fits of major type, averaging ten a month, and sometimes followed by periods of mental confusion with hallucinations. Intelligence quotient 0·84. Luminal started at age of 20 years. Fits continued for nearly two months and then suddenly stopped, and have remained in abeyance for three years. Former tendencies to bad tempers and antisocial conduct generally have largely disappeared under luminal.

Luminal Medication and the Age of the Patient.

In order to determine whether there is any relation between age and the response to luminal treatment, the 167 patients were divided into five-year groups, according to their ages when the drug was started and the effect on the incidence of fits was noted for each age-group as follows:—

Age in years	5–10.	11–15.	16–20.	21 or over.
Number of cases	16	85	34	32
Permanently benefited	56%	25%	29·5%	31%
Benefited for more than three months	19%	28%	32%	41%
No effect	12·5%	42%	29·5%	25%
Harmed	12·5%	5%	9%	3%

These figures show that the best results are to be expected in early life, and that in later years the drug is likely to have less effect either for good or ill.

Investigations were also carried out to see if the duration of the disease, the age of onset of the disease, or the sex of the patient had any influence in determining the response to luminal, but the results were inconclusive.

Incidence of Fits during Administration of Luminal.

The average number of fits per month was first determined in 157 cases who had had luminal-sodium for six consecutive months.

Months of administration	1st.	2nd.	3rd.	4th.	5th.	6th.
Average number of fits	2·8	3·83	4·55	4·02	4·25	4·8

Then the average number of fits per month in four six-monthly periods was determined in 65 cases in which luminal had been given for at least two years.

Half-yearly periods	1st.	2nd.	3rd.	4th.
Average number of fits	3·47	4·18	4·73	5·33

Finally, the average number of fits per month in eight six-monthly periods was determined in 24 cases in which luminal had been administered for at least four years.

Half-yearly periods	1st.	2nd.	3rd.	4th.	5th.	6th.	7th.	8th.
Aver. number of fits	3·25	3·95	3·63	3·9	4·45	4·0	4·13	4·6

The comparatively low average number of fits in the last group of figures is, of course, accounted for by the fact that only cases which have made some improvement with luminal have continued to have it for so long as four years. These figures seem to show beyond any doubt that an acquired tolerance to luminal-sodium is the rule. It must set in pretty rapidly in many cases, but in others, though slow, it is progressive.

These results are in direct contradiction to those obtained by Patterson, Damon, and Levi, of the Craig Colony.[1]

Effect of Stopping Luminal upon the Incidence of Fits.

The administration of luminal has been stopped in a large number of cases because the drug has been useless, or because its period of usefulness has appeared to be over. In two cases the occurrence of rashes has led to the discontinuance of the drug. In a few cases mental alterations, as evidenced by abnormal conduct, have been the cause of luminal being stopped. Periods of abnormal conduct, however, not infrequently occur in epileptics apart altogether from any form of medication, and one should hesitate to ascribe them to any particular drug. Careful scrutiny of these cases in the light of their history, both before and after the period of luminal administration, leads to the belief that probably in only three or four were the mental alterations the outcome of the drug treatment.

The effect of stopping luminal on the incidence of fits is remarkable. In the first month after luminal was stopped, out of 65 cases 72·5 per cent. had more fits than the monthly average during the period of luminal administration, in 20 per cent. the incidence was the same, while in only 7·5 per cent. was it less. In many of the cases where there was a marked increase in the number of fits, luminal treatment was resumed in a few weeks. Even after these cases have been eliminated the incidence of fits in the remaining 45 cases, in which there is a record covering at least six months after the end of luminal treatment, shows an extraordinary rise. The average number of fits per month before luminal was started was 8·1, during luminal treatment was 6·5, and after luminal was stopped was 10·8.

If the cases be taken individually it becomes clear that in about 50 per cent. of the cases the effect of a limited period of luminal administration has been to leave the patient definitely worse off than he was before. It is worth noting that although a considerable increase of fits has followed the cessation of luminal treatment in so many cases, in only one case has the increase been of an order serious enough to endanger life.

CASE 10.—A young man of 19 was a bad case of epilepsy upon whose fit-incidence luminal-sodium had had but a transient effect. Accordingly, after seven months it was discontinued. A fortnight later the patient had a status epilepticus lasting several hours from which he only just recovered. He had had one attack of status previously.

The Effect of Luminal-sodium on the Mind.

Luminal is a sedative, and it was only to be expected that the immediate effect of giving luminal, even in the small doses used at Lingfield, would be to make the patient a little more sleepy and dull than usual. Such an effect was noted in a small proportion of the cases. It was never very marked, and as a rule it passed off in a few days. In no case was it serious enough to necessitate the cessation of treatment.

Other effects of luminal medication upon the mind and therefore of the conduct of patients, dramatic and far-reaching as they may have been, were, in my opinion, secondary to reduction or arrest of the fits. It is impossible to foretell what will happen if, in a chronic case of epilepsy with frequent attacks, the fits are suddenly arrested; and, as will have been made clear by the foregoing figures, luminal, if it is going to act at all, usually acts quickly. In nine cases out of ten the result is altogether favourable. The patient is brighter, his interest in his environment increases, his bad tempers are fewer and slighter, his asocial conduct tends to disappear. The consciousness of freedom from fits undoubtedly increases his happiness. In a small minority of cases, however, effects of a very different kind may be observed. That these may be varied, in quality and duration, may, perhaps, be best demonstrated by a short account of a few cases.

CASE 11.—A girl of 13 was having major fits at the rate of three in two days, as well as slighter attacks, when she was put on luminal. The major attacks stopped at once and the girl's mental condition, never too stable, rapidly changed for the worse. She refused to get up, but lay in bed, incontinent, noisy, and confused. After five days the luminal was stopped and the patient quickly regained her normal condition.

CASE 12.—The patient, aged 13, was also a troublesome girl who was prone to react to anything that interfered with her wishes by prolonged howling. At the time luminal was started she was having major fits at the rate of 12 a month. The fits stopped at once but the mental instability gradually became more evident, tempers were more frequent, and violence began to appear. Two months later an attack of acute mania necessitated a hypodermic of morphia followed by a few days in bed and some sulphonal. A fortnight after matters came to a climax. The patient became obstructive and abusive. She refused food, broke windows, and retreated under her bed, biting and kicking any who had the temerity to approach her. Sedatives in rather large quantities were called for and the luminal was stopped. The mental condition slowly subsided and the fits returned in a few days' time. In the 18 months that have since elapsed there has been no recurrence of mania or of such marked antisocial conduct, though the patient remains a difficult one to deal with.

CASE 13.—A long-established resident at the colony had been a troublesome school-boy and adolescent, with an

[1] Patterson, H. A., Damon, Le G. A., and Levi, P.: A Comparative Study of Various Methods of the Administration of Luminal in Epilepsy, Jour. Nerv. and Ment. Dis., 1926, lxiii., 446–455.

mperfectly controlled temper. At the age of 23, when he had a pretty regular incidence of four major attacks a month, luminal medication was begun with consequent mmediate cessation of all attacks. His conduct gradually became more and more abnormal. Violent tempers followed nsignificant provocations. He attacked other patients and finally knocked down a lady member of the staff, and after six months of luminal treatment had to be removed from the colony.

It will be observed that all these cases showed mental instability and asocial tendencies prior to the administration of luminal, and the exaggeration of these was, I believe, not directly due to the luminal itself, but was secondary to the arrest of their fits. It is cases of this type that has, I imagine, led various writers to assert that in arresting his fits by means of drugs we are doing an epileptic a grave disservice. That this was so in these cases is obvious enough, but to apply this dictum to epileptics generally is manifestly absurd. Anyone with much experience of epilepsy must have seen a rapid and progressive deterioration, mental and physical, cut short by an arrest or reduction of the fit-incidence by means of drugs.

Two other cases which present some unusual features may be recorded here.

CASE 14.—A girl, aged 7½, was subject to major fits at the rate of 23 a month, and was an exceedingly troublesome child. On 1 gr. of luminal-sodium daily the fit-incidence was reduced to eight a month, with a corresponding improvement in behaviour. At the end of three months, however, she became tolerant to the drug. Incontinence, apart from fits, reappeared and she became as noisy, mischievous, and restless as before. At the end of six months the daily dose was increased to 2 gr. The result was dramatic. The attacks stopped at once and her behaviour improved as though by a miracle. This happy state of affairs lasted for exactly a year. Unfortunately, the further sequence of events was not so favourable, but is of interest. Slight attacks without complete loss of consciousness began to manifest themselves and continued to do so irregularly at the rate of about five a month for a further period of two years. During this period her asocial tendencies slowly but surely began to get the upper hand again, and were, I think, accentuated by the early onset of menstruation. Periods of bad temper became more frequent and increasingly violent. She bit, scratched, and attacked those around her and tore her own clothing in shreds, and finally had to be removed from Lingfield on account of the grave detriment her presence caused to others. The major fits never returned. I am not inclined to think that luminal had any prejudical effect on this case; its effect for the first 18 months was clearly most favourable, and it served to delay for two or three years the development of a grave mental instability that was probably inevitable.

CASE 15.—A frail, undersized girl, aged 13, had a very large number of fits, both major and minor. After four and a half years at the colony she had made no progress; rather was it clear that she was pretty rapidly deteriorating mentally and physically. A daily dose of 2 gr. of luminal-sodium was started and in ten days there was a complete cessation of fits of all kinds. Within the same period there was a most extraordinary change in the girl's character. She became very irritable and miserable, at times indulging in copious crying, at other times insolent and making false charges against other girls. Gradually these temperamental changes became less noticeable and the patient became happier and more amenable to ordinary life. At the same time her physical condition improved dramatically. Before luminal was started her average gain in weight had been 1 lb. a year, but she now put on nearly a stone in five months. After four months of luminal administration two isolated major attacks occurred, and four weeks later a series of fits began which culminated within seven days in status epilepticus, hyperpyrexia, and death. There was no previous history of status in this case, and it looks as if luminal in arresting the fits had stored them up, as it were, until the breaking-point was reached and they descended like an avalanche with fatal result.

If this is the sequence of events it is a very rare one. Nothing similar is found in any of our case-histories at Lingfield. The nearest approach to it occurred in a girl of 9, who during five months of luminal treatment had monthly attacks of what were, in effect, status epilepticus lasting about an hour and a half, and who, when the luminal was stopped, reverted to four or five isolated majors a month.

Rashes.

Only two cases of rashes due to luminal have been observed. The first occurred in a girl of 15. Ten days after luminal was started a very marked erythema with raised papules appeared on the arms. The appearance was of measles superimposed on scarlatina. There was no rise of temperature. The drug was stopped, and the rash disappeared completely in a few days. A second case occurred in a boy of 12. The rash was exactly similar, but manifested itself within 24 hours of the first dose, and was widespread over the body and limbs. The drug was immediately stopped, but the papules were still visible, chiefly on the forearms, two or three weeks later.

The Effect of Luminal on Different Kinds of Attacks.

Like bromide, luminal is most effective in controlling major fits; automatism and momentary attacks of petit mal are much more resistant to medical treatment, though gratifying results with these do occur. It sometimes happens that with the reduction or arrest of the major attacks the slighter ones become more frequent, the process being reversed if the luminal is stopped. A very interesting case of the familial myoclonus of Unverricht showed this sequence of events most clearly. Luminal was given a good trial for two periods. Each time the major attacks were much fewer and the myoclonic spasms worse; as soon as the luminal was stopped the major attacks reappeared in large number, and the spasms were less. In this case the myoclonus was by far the most serious feature, and the patient was happier without luminal.

The Value of Luminal-sodium given Intermittently.

In one female patient, when the attacks almost always just preceded the menstrual period, luminal was given from the sixteenth day after the start of one period up to the commencement of the next. The result was unsatisfactory. The fits held off during the period of luminal administration, only to appear later, and the total fit-incidence, after three months' trial, was increased. On continuous daily doses a striking reduction in the fits was subsequently obtained. Luminal-sodium in isolated doses up to 5 gr. has been given after the first fit to several patients who usually have a large number of fits in succession. The adoption of this measure has very often been successful in preventing the occurrence of further fits. I have also used the drug hypodermically in doses of from 2–6 gr. in cases of status epilepticus. It is very hard to say how far the course of events in this condition is modified by any treatment. My general impression is that luminal has not been of much avail.

The Value of a Second Period of Administration.

In a few cases where the drug has been discontinued as of no value, a second attempt to control the attacks by luminal-sodium has been made. The fact that the second attempt, with the same dosage, is often more successful than the first seems worth putting on record. It is difficult to see why this should be.

Summary.

This paper records the effect of small doses of luminal-sodium on a series of epileptics whose condition has failed to improve on other methods of treatment.

In the majority of cases benefit was obtained at first, but if the fit-incidence over periods of weeks, months, or years be studied, it is apparent that there was a progressive tolerance, sometimes slow, sometimes rapid, to the drug. In about 1 case in 20 complete and probably permanent arrest of all seizures occurred. These favourable cases showed no features in common which would enable us to define a type of case likely to benefit by the treatment.

Whether the administration of luminal was of value or not, stopping it was almost always followed by an increase of fits, the incidence often being higher than before luminal was started. This is a serious feature of luminal medication.

Grave mental alterations following on the use of luminal occurred but they were rare, and it is submitted that they were the direct result of the abrupt cessation of attacks in chronic epileptics, rather than of luminal itself.

Rashes were only observed in two cases.

The investigations go to show that luminal is a drug that should be used with caution in epilepsy. It should not be prescribed unless there can be careful supervision of the patient's behaviour as well as an accurate fit record. An immediately favourable effect is no criterion of ultimate benefit. It may be justifiable to take some risks to find out whether the patient is one of the few fortunate ones whose fits will be permanently arrested by the drug, but the fact that risks are involved and that harm, not good, may result, should never be out of the physician's mind.

THE INFLUENCE OF ORAL SEPSIS UPON CARBOHYDRATE TOLERANCE IN NON-DIABETICS:

EFFECT OF SUBSEQUENT DENTAL TREATMENT.*

BY W. HOWEL EVANS, M.B., B.Sc. LIVERP.,
LECTURER IN PATHOLOGY, UNIVERSITY OF LIVERPOOL;
D. RIDING, M.D. LIVERP., M.R.C.S. ENG.,
FORMERLY HOLT FELLOW IN PATHOLOGY;
AND
ERNEST E. GLYNN, M.D. CAMB., F.R.C.P. LOND.,
PROFESSOR OF PATHOLOGY, UNIVERSITY OF LIVERPOOL.

THE power of focal infections to disturb sugar metabolism has been frequently noted in recent years, though precise observations are still scanty. Long before the general clinical use of blood-sugar estimations it was recognised that a carbuncle might be associated with glycosuria, also that the latter might disappear when the carbuncle healed. It was also noted that dental diseases such as caries and "pyorrhœa" were frequently associated with diabetes. The usual explanation was that the diabetes lowered the patient's resistance, but others thought that chronic sepsis anywhere, including the mouth, might sometimes cause diabetes.

Sir William Willcox [1] writes: "Streptococcal and other toxins may cause a toxic glycosuria, probably by impairment of the endocrine function of the pancreas. Dental sepsis is undoubtedly a factor in the causation of glycosuria in some cases, and it should always be removed in cases of diabetes. A rise in the carbohydrate tolerance has often been observed by me after the removal of dental sepsis in early cases of diabetes." Willcox also states: "It seems probable that diabetes mellitus is caused in some cases by irrecoverable damage to the islets of Langerhans by toxic absorption from dental sepsis."

The study of diabetes has been assisted in recent years by testing the carbohydrate tolerance with the help of blood-sugar curves, following the oral administration of 50 to 100 g. of glucose. This test has also been applied to studying the tendency to glycosuria in those with focal infections or other pathological lesions. Thus, Pemberton,[1] of Philadelphia, used it in many cases of rheumatoid arthritis among American soldiers and found a decreased carbohydrate tolerance in the majority. The degree of failure was proportional to the severity of the cases. He noted that in two cases where the focal infections of tonsillitis and dental abscesses respectively were present, the tolerance was restored to normal on the ablation of the foci. He also shows clearly by means of his blood-sugar curves, that the impaired tolerance continued in the chronic cases after the removal of all demonstrable foci of infection. This suggests that the prolonged action of a toxæmia may bring about a persistent physiological failure of the pancreas; in other words, may lead to the establishment of true diabetes mellitus. Pemberton remarks "Lowered glucose tolerance rests on fundamental pathological processes. It seems to stand in some relation to inflammatory processes at large, and it appears from the data adduced herewith that the incidence of an inflammatory process in a normal person may induce an impaired tolerance." Gay and Olmsted,[3] using the glucose-tolerance test in many diverse conditions, confirmed Pemberton's results in acute and febrile states of arthritis; Gay also noticed impairment of carbohydrate tolerance in furunculosis, so did Gettler and St. George. Holcomb [5] reports two cases of "diabetes" where carbohydrate tolerance was improved by removal of septic foci. The first was a clear-cut case of diabetes mellitus which was markedly improved by treatment of septic maxillary antra. The second case is more important from our point of view. The patient, when first seen, showed a disturbed blood sugar curve and had the clinical symptoms of polyuria, &c., pointing to diabetes mellitus. But after extraction of septic teeth with abscesses and the removal of a chronically inflamed appendix, the tolerance, according to the published figures, became entirely normal. This suggests that the disease was not true diabetes, but an example of toxic impairment of carbohydrate tolerance. Sansum (quoted by Holcomb) noted impairment of tolerance in a case of acute tonsillitis. Pringle and Miller [6] studied a large number of arthritics at Bath and confirmed in general Pemberton's findings of a lowered carbohydrate tolerance in this condition. They agree with him that the extent of impairment is parallel to the severity and that the tolerance returns to normal with convalescence—most rapidly when infected foci have been discovered and removed. They particularly mention three cases of impaired tolerance becoming normal after tonsillectomy and one after dental extractions for an apical abscess.

Present Investigation.

No one, so far as we are aware, has systematically studied the effect of oral sepsis and of its subsequent treatment, upon carbohydrate tolerance in non-diabetic patients, as measured by the blood-sugar curve following a standard dose of glucose. It was therefore decided to investigate a series of patients presenting the commoner types of oral sepsis, but without evidence of diabetes.

The patients were newcomers to the clinic of the Liverpool Dental Hospital. They were first examined and selected by Prof. W. Gilmour (the Warden), or his assistant who made the dental diagnosis. They were then examined by D. R. or H. E. as regards their general clinical condition, especially anæmia, dyspepsia, arthritis, or asthenia. The glucose-tolerance test was arranged as soon as possible and carried out in the Thompson Yates Laboratory of Pathology. The patients were asked to take a breakfast consisting of one cup of tea, one round of bread or toast, and one egg or one rasher of bacon and to report for the test two and a half hours later. The blood was taken from the finger with a MacLean pipette; a "fasting" sample was first collected, then 50 g. of glucose in 100 c.cm. of water administered, and further samples collected at half-hourly intervals up to two hours. The blood-sugar was estimated by the Folin-Wu technique.

We were reluctantly compelled to omit systematic urine tests because a number of our patients were women and there were no facilities. But the blood-sugar estimations afforded a very reliable indication of carbohydrate tolerance. The first glucose-tolerance test in each patient served two purposes: (*a*) to give the original state of carbohydrate tolerance, and (*b*) to exclude diabetes mellitus. None of our patients gave a curve which could be construed as diabetic; further, as clinical symptoms of diabetes were completely absent, they have been classified as non-diabetic.

After the test the patients were put under dental treatment and inspected from time to time. When Prof. Gilmour certified great improvement or a cure

* This investigation was carried out on behalf of the Dental Board of the United Kingdom, who assisted by means of a small grant.

he second tolerance test was done. The patients' ecords were kept on special printed forms. The ffect of oral sepsis upon the level and type of the lood-sugar curve was estimated in two different ays:—first by comparing the curve in the same atient before and after dental treatment; second y comparing the curve of the patient before or fter dental treatment with a "control average urve" from nine normal persons, also tested with 0 g. of glucose.

In order to simplify the task of comparing the hole test of one patient with that of another, the verage number of milligrammes of sugar present i the five separate estimations was calculated—viz., ne "combined estimation" (see Table I). This verage is, however, only a rough indication of the alue of the blood-sugar curve, for it does not show ne fasting level, the type of curve, nor the level fter the test.

The investigation was begun by D. R., and con-nued and completed by H. E., who also tested the ine normals. It was hoped to investigate many al sepsis patients, but they were extraordinarily luctant to undergo the carbohydrate tolerance st; several refused point blank. After exasperating isappointments, 11 were tested before treatment uring about six months. Eight of these were again sted after treatment; five were said to be cured nd three greatly improved. The average time etween the first and second tests was six months, ne longest eight months and the shortest four months. he remaining three patients refused to submit to a econd tolerance test, one female alleging that the rst test had seriously damaged her health.

With a view to diminishing the number of examina-ons required, the X ray picture of each patient, riginally decided upon, was dispensed with.

Clinical Histories.

CASE 1.—Female, aged 16. Seen Jan. 28th, 1926. Acute veolar abscess for three days (right upper first bicuspid). eadache; temperature 103° during tolerance test. Treat-ment: bicuspid extracted. Re-examined July 4th, 1926. "Mouth healthy."

CASE 2.—Male, aged 41. Seen April 14th, 1926. Large acute alveolar abscess "for few days" (right second lower molar). Several carious teeth. General pyorrhœa. "Some asthenia." Treatment: molar extracted. Ultra-violet rays. Re-examined Sept. 6th, 1926. Abscess healed. Pyorrhœa slight. Patient feels much better.

CASE 3.—Female, aged 11. Seen Jan. 22nd, 1926. Acute alveolar abscess "for few days" (right lower first molar). Extensive caries. A little subacute gingivitis. Abscess burst. Treatment: mouth washes. Right and left first lower molars extracted. Ultra-violet rays. Re-examined Sept. 4th, 1926. "Mouth healthy."

CASE 4.—Male, aged 19. Seen Jan. 21st, 1926. Chronic alveolar abscess three weeks (right upper first bicuspid). History of repeated abscesses. Five carious teeth. Some anæmia and asthenia. Treatment: bicuspid extracted. Carious teeth filled. Re-examined June 23rd, 1926. "Mouth healthy."

CASE 5.—Male, aged 18. Seen June 6th, 1925. Painful bleeding gums, acute membranous gingivitis and pharyngitis (Vincent). Treatment: local and ultra-violet rays. Re-examined Feb. 9th, 1926. General condition much improved. Mouth much improved, slight gingivitis round left upper lateral.

CASE 6.—Female, aged 55. Seen Feb. 16th, 1926. "Pyorrhœa," painful gums five years, much worse last three months. General suppurative gingivitis, specially around upper right molars which were loose. Slight anæmia and loss of weight. Treatment local to gums and ultra-violet rays. Re-examined June 18th, 1926. "Marked improvement. With a little local scaling and filling mouth should be quite healthy."

CASE 7.—Male, aged 64. Seen June 10th, 1925. "Pyorrhœa," painful gums round remaining four teeth in upper jaw; chronic gingivitis, teeth loose. Rheumatic pains in knees. Treatment: all teeth extracted. Re-examined Feb. 2nd, 1926. Gums quite healed. Feels well; gained one stone.

CASE 8.—Male, aged 30. Seen April 7th, 1926. Sore gums for three months. "Typical subacute suppurative gingivitis." Pockets teeth good. Some anæmia. Treatment: local. Refused second tolerance test. There is no record as to the loss or looseness of teeth in this case, but a hospital

* Pyorrhœa.

patient with "sore gums for three months" and "pockets" would almost certainly have "pyorrhœa"; he has therefore been classified with the other cases of "pyorrhœa." The patient is now at sea.

CASE 9.—Female, aged 21. Seen August 20th, 1925. "Pyorrhœa." Also acute abscess; teeth very carious. Extractions and local treatment to gums. Refused second tolerance test.

CASE 10.—Male, aged 50. Seen July 24th, 1925. Extensive necrosis left lower jaw following extraction of 25 teeth. Slight anæmia and asthenia, rheumatic pains in knees. Treatment: mouth irrigation, removal of sequestra and remaining stumps. Re-examined Feb. 9th, 1926. "General condition improved. Mouth entirely healed."

CASE 11.—Female, aged 30. Seen June 10th, 1925. Suppuration of socket and swelling of jaw following extraction left lower bicuspid 12 days before. Treatment: local. Refused second tolerance test.

Discussion of Results.

MacLean,[7] whose practice we followed in using 50 g. of glucose for the tolerance test, attaches special importance to three points in the blood-sugar curve: (1) the fasting level which should not exceed about 100 mg.; (2) the summit, which should not exceed 160 to 170 mg.; (3) the original, fasting level should

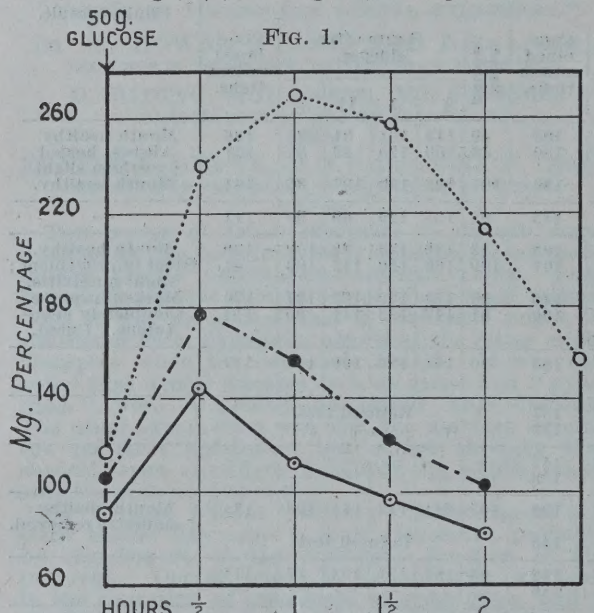

FIG. 1.

Carbohydrate tolerance test. Chart showing "average" blood-sugar curves of nine normal persons (bottom curve), of 11 cases of oral sepsis before treatment (middle curve), and of one case of moderately severe diabetes (top curve).

be reached or nearly reached by the end of the two-hour test. The marked differences in these points between a patient with moderately severe diabetes and a normal are well shown in Fig. 1.

Our 11 patients with oral sepsis have been roughly divided into three groups, though some were difficult to classify: (1) alveolar abscess, four cases, three acute; (2) gingivitis, five cases, one acute (Vincent), and four "pyorrhœa"; (3) post-operative suppuration and necrosis, two cases. The results of all the tests and of the normal control test are shown in Table I. The average figures for the 11 patients, given in the last line but one of the table, when compared with those of the control (last line of the table), show a slight but definite diminution in carbohydrate tolerance (see Fig. 1). The average "combined estimations" also show a diminution, being 136 mg. compared with 106. Figures obtained before treatment in the eight cases in which the tests were afterwards completed are very similar. But the average of their second tests show a definite improvement in tolerance (see table). Further study of the results reveals striking differences between the three groups of patients, these are summarised below.

Group 1.—The three cases of acute alveolar abscess (Cases 1–3) showed a marked diminution in tolerance, the greatest in the three groups. The average of each separate estimation is definitely higher than that of

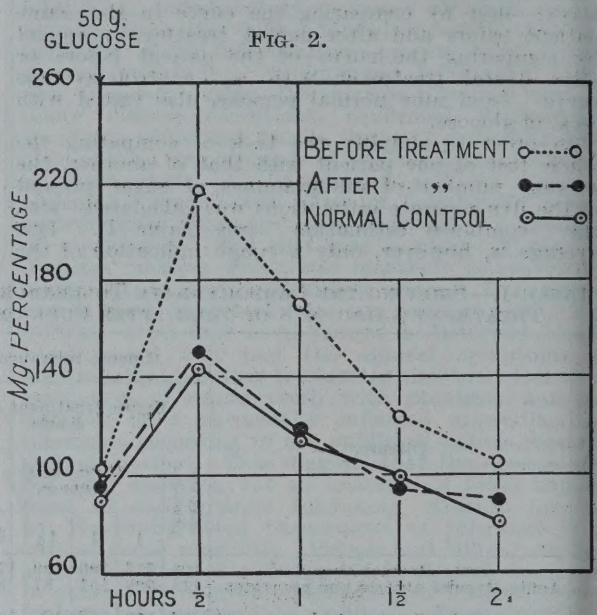

FIG. 2.

Carbohydrate tolerance test. Chart showing average blood-sugar curve of nine normal persons, also of three cases of acute alveolar abscess both before and after dental treatment.

the control by 7 per cent., 74 per cent., 57 per cent., 24 per cent., 20 per cent. respectively and the "combined estimation" by 37 per cent. The curve, however, is unlike that in a moderately severe case of diabetes (Fig. 1) notably in the lower fasting level, the pointed summit and the rapid fall resulting in a return to the original level at the end of the test. In Case 1, that of a female whose temperature was 103° during the test, the high level of the curve indicates that glycosuria must have been present about the end of the first half hour, the normal renal threshold for glucose being about 180 mg. per cent. After treatment, which cured the abscess in all and greatly benefited the pyorrhœa in Case 2, the

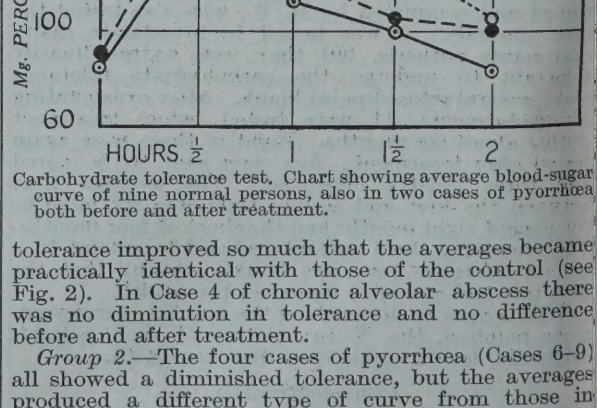

FIG. 3.

Carbohydrate tolerance test. Chart showing average blood-sugar curve of nine normal persons, also in two cases of pyorrhœa both before and after treatment.

tolerance improved so much that the averages became practically identical with those of the control (see Fig. 2). In Case 4 of chronic alveolar abscess there was no diminution in tolerance and no difference before and after treatment.

Group 2.—The four cases of pyorrhœa (Cases 6–9) all showed a diminished tolerance, but the averages produced a different type of curve from those in Group 1. The fasting level was higher than the control's—viz., by 26 per cent., and the fall was

delayed so that the summit of the curve became somewhat flattened and began to approximate to the diabetic type (see Fig. 1). In Cases 6 and 7, tested twice, the curve before the treatment was similar. After treatment, however, the tolerance improved and was only slightly less than the control's (Fig. 3). The failure to improve quite as much as in the alveolar abscess after treatment is, perhaps, partly due to age, for in later years sugar tolerance tends to diminish. Thus the cases of pyorrhœa averaged 59 years and of alveolar abscess only 22 years.

The differences in tolerance which have emerged in patients of these two groups would have been greater had the tests been made with 100 g. of glucose instead of 50 g. In Case 5 of acute membranous gingivitis and pharyngitis (Vincent) the tolerance was apparently less after cure than before, the combined estimations being respectively 107 and 127. This may be due to some difference in the patient's diet before the sugar test or to the failure to take the prescribed breakfast. Both, however, are normal curves.

Group 3 comprises two cases of post-operative suppuration and necrosis. The tolerance in Case 10 (a man of 50) was practically the same before and after treatment, while that of the other patient, which was distinctly diminished, was not tested again.

Summary and Conclusions.

1. Evidence has been produced from a study of 11 cases that oral sepsis in non-diabetic patients is usually associated with slight but definite diminution in carbohydrate tolerance. 2. This diminution was greater in the three cases of acute alveolar abscess than in the four of pyorrhœa. 3. Subsequent dental treatment of five of these seven cases, which cured or greatly improved the oral disease, was associated with an increase in tolerance, so that it practically equalled the tolerance of the normal control. This improvement from treatment is evidence that the oral sepsis *caused* the diminution in carbohydrate tolerance. Such a depression might, if prolonged, perhaps lead to glycosuria or even to diabetes.

MULTIPLE CAVERNOUS ANGIOMATA OF THE SWEAT DUCTS

ASSOCIATED WITH HEMIPLEGIA.

BY B. W. CROWHURST ARCHER, M.B., CH.B. ST. AND.,

SENIOR HOUSE PHYSICIAN AND IN-PATIENT REGISTRAR, WEST END HOSPITAL FOR NERVOUS DISEASES.

THE case which is about to be described would seem to be one of congenital multiple cavernous angiomata of the sweat ducts, associated with, but not due to, syphilis in a man 30 years of age, with a history of two hemiplegic attacks and symptoms of cerebral softening and hypothyroidism. The condition is sufficiently unusual to make a full account of interest.

The patient, male, aged 30, is the fifth child of a family of 11. The mother and father are both alive and well, and their Wassermann reactions are negative. Three of the children have died, the first two of meningitis at the age of 12 months and the youngest of tuberculous peritonitis. One brother shows the same skin condition as the patient.

The patient was a weak child, but states that the only illness he has had up to the age of 21 years was measles. He has never felt well, however, and has suffered from frequent attacks of bilateral frontal headache. He was rejected from the army in 1915. In 1918 he felt so run-down that he gave up work, and later in the same year he developed a right hemiplegia. He was then 21. The attack came on during the day, was sudden in onset, and preceded by no illness. Speech was not affected, and complete recovery took place in two years. In 1922, at the age of 25, he had a similar attack, but in addition there was involvement of the left side of the face and loss of speech. There was no loss of consciousness in either attack.

Since the last stroke, from which he has completely recovered, he has suffered from general debility and nervousness, and complains of generalised pains in the back and all four limbs, which he states have been continuous for the last eight years.

Condition on Examination.

The patient gives a general impression of mental dullness. Speech and articulation are normal. He is slow in all his movements, and complains of always feeling cold.

The optic discs show a varicose and degenerated condition of the retinal vessels but no hæmorrhages. The visual fields are full. The pupils are equal, circular and central, and react to light and convergence. The other cranial nerves are normal. There is no disorder of sensation or coördination. The upper and lower teeth can only be separated for about one inch. The jaw-jerk is present and the other reflexes are normal. The heart and other viscera are healthy. The temperature is usually about 98° F., and the average pulse-rate is 90. The blood pressure is 115 mm. Hg systolic and 90 mm. diastolic.

The *skin* shows multiple small pinhead disseminated angiomata distributed over the lower thorax, abdomen, lateral aspects of trunk, buttocks, thighs, and genitals. The arms and upper thorax are free. The mucous membrane of the lips, cheeks, and soft palate are also involved, but not the tongue. The spots are somewhat purplish in colour, and in some cases coalesce to form larger plaques. They are present in enormous numbers as if the skin had been peppered—a few appear purpuric owing to rupture either spontaneously or through slight traumatism, but none are of the well-known spider nævus type, which bleed externally when injured. There is a small nævus on the right upper eyelid and a yellowish-brown mole over the right clavicle. The condition is a congenital angiomatous one and not purpuric, the vascular spaces being apparently situated round the sweat pores.

The blood flowed readily from the ear and was distinctly pale and watery. The blood count shows 5,390,000 red cells and 9400 white cells per c.mm. The hæmoglobin is 59 per cent. and the colour-index is 0·55. Differential leucocyte count: polymorphs, 72·5 per cent.; lymphocytes, small, 21·5 per cent.; large, 4·5 per cent.; total, 26·0 per cent.; and large mononuclears 3·5 per cent. Eosinophils 1·0 per cent., but no mast cells. The films show general diminution in the size of the red cells with moderate anisocytosis. The blood on first examination yielded a negative W.R., but there was about half an hour's delay in the rate of hæmolysis. On second examination, taken 24 hours after a provocative intravenous injection of novarsenobillon, the W.R. showed a weak positive reaction with 4 M.H.D.'s of complement and quite definite as compared with negative sera. The cerebro-spinal fluid, which was under excessive pressure, shows 4 cells per c.mm., practically all small lymphocytes, with a very occasional endothelial cell. Total protein 0·04 per cent. Globulin, slight excess. Wassermann reaction, a weak positive reaction with about 4 M.H.D.'s of complement. Lange's colloidal gold curve was of the luetic type, 1233321000.

The X ray photographs of the skull show slight thinning of the bone in the right temporal region.

Histological Examination.

An excised piece of skin was fixed in formalin and put through for paraffin section—stained with hæmatin and eosin and by v. Gieson's method. Each section of the area, about ¾ inch long, shows one or two, and occasionally three, of the little subcutaneous vascular patches. They consist of, in section, some two, three, and four little irregular "cavernous" spaces, very much like those seen in a cavernous angioma of the liver, with connective tissue septa and walls, and a rather indefinite layer of lining cells, probably flattened endothelial cells, which are at some places fairly distinct with nuclei projecting slightly into the lumen, like ordinary vascular endothelium—but at other parts they are somewhat indefinite and at others apparently wanting—the wall at these places being formed distinctly by connective tissue. The tissue was extremely tough and difficult to cut, and it is a little difficult to decide whether some of the lining has been lost during the cutting and staining. The little "cavernous angiomata" appear to be situated at or near the openings of the sweat ducts. They are mostly situated just under the epithelium which is distinctly thinned over them, but in the connective tissue of the corium there is considerable hyperkeratosis of the adjacent epithelium, and also increased density of the connective

tissues of the surrounding cutis vera. The acini of many of the sweat glands are very irregular in size, some appear fairly normal, but, in the same group, other acini are dilated to a varying degree, from slightly—and with cubical to almost columnar epithelium, occasionally more than one layer deep—to more dilated spaces, almost small "cysts," lined with much more flattened epithelium, in some instances almost atrophied to the disappearing point. In one gland there was one small vascular space immediately adjacent to the acini, which very closely resembled the more superficial cavernous spaces, but this was exceptional, and this particular gland may be of some interest in the ætiology of

Section showing vascular space in relation to the opening of a sweat duct, epithelial keratosis, and a small cavernous vascular space resembling the more superficial ones adjacent to the acini of a sweat gland.

the condition. There appears to be no analogous condition of the sebaceous glands or of the hair follicles.

In most of the cavernous spaces there was a distinct excess of polymorphs, and the blood in some of the spaces was thrombosed. There were no surrounding "nævoid" cells, but a few polymorphs were also found in the surrounding connective tissue, indicating some slight inflammatory reaction. There was some extravasated recent blood amongst the loose cells of the stratum corneum, but this is probably "operative" in origin.

Conclusion.

The varicose and degenerated condition of the retinal vessels leads one to consider the possibility of similar involvement of those of the cortex as is frequently found in adenoma sebaceum. This might explain the dementia and the unusual age at which the hemiplegic attacks occurred—the result of hæmorrhages or thromboses. It is of interest while considering the patient's mental condition to call to mind that mental depression, which was a marked feature in this case, is a frequent symptom of affections of the sweat gland apparatus—i.e., lichen planus. From the endocrine standpoint the dryness of the skin, the pains in the limbs, situated near but not in the joints, the dull mental depression, the slowness of movement, and the constant chilliness seem to point to a diminished thyroxin secretion. The mother's W.R. being negative, as is that of the brother showing the same skin condition as the patient, would seem to indicate that the vascular lesions are not related to syphilis.

I am indebted to Dr. W. E. Carnegie Dickson, pathologist to the West End Hospital, for the micro-photograph and his kind help in the laboratory investigations, and Dr. Hildred Carlill for permission to publish the case.

AN INVESTIGATION INTO THE RESULT OF X RAY TREATMENT OF PRIMARY MALIGNANT INTRATHORACIC TUMOURS.

BY F. G. CHANDLER, M.D. CAMB., F.R.C.P. LOND.
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, CHARING CROSS HOSPITAL; PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK, E.;
AND
CARLYLE T. POTTER, M.D., C.M. MCGILL,
CLINICAL ASSISTANT, CHARING CROSS HOSPITAL.

THIS investigation was suggested by a case in which there appeared to have been a temporary disappearance of a sarcoma of the lung under X ray treatment. The details are as follows.

In June, 1914, a boy, A. A., aged 12, was admitted to the London Hospital. He was well until January, 1914, when he began to lose weight and to have night sweats. In April the mother noticed lumps appearing on the right side of the chest. On admission the child was wasted, the apex beat was in the left midaxillary line, there was dullness over the right side up to the second rib, and a network of greatly enlarged veins over the right chest and abdomen. Over the fifth and sixth ribs on the right side, just outside the nipple line, were two lumps the size of walnuts. A diagnosis of sarcoma was made. Under X ray treatment by Dr. Gilbert Scott the lumps and the enlarged veins disappeared completely, the heart returned to its normal position, and the chest became relatively resonant. He was discharged to a convalescent home in August greatly improved, and in September appeared to be well with no symptoms. In June, 1915, to our intense disappointment he returned to the hospital again, desperately ill, and died. At the post-mortem examination mediastinal sarcoma was found invading the lung, mediastinum, and pericardium.

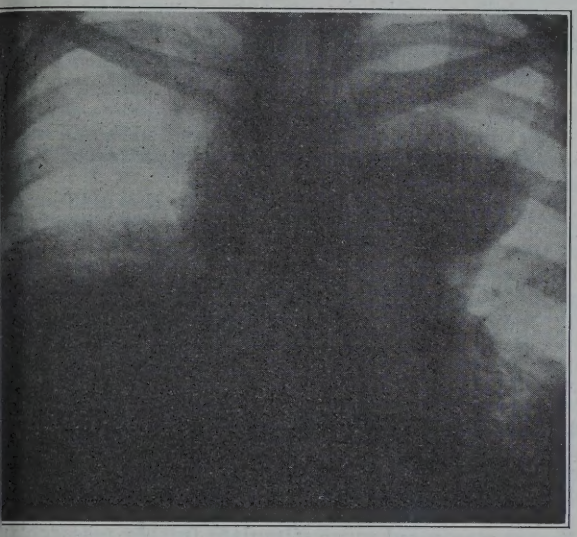
Since then, though we had known of temporary disappearance, no example of recovery from a malignant intrathoracic tumour had come under our notice. We therefore decided to investigate a number of cases in order to determine whether X ray treatment was ever curative, whether it prolonged life, or caused amelioration of symptoms.

Material.

Our material consists of 120 cases from St. Bartholomew's, Charing Cross, and the London Hospitals, and private cases. The hospital cases were under the care of the following physicians: Dr. James Calvert, Dr. Chandler, Lord Dawson, Dr. Morley Fletcher, Dr. David Forsyth, Prof. F. R.

Fraser, Dr. A. E. Gow, Dr. George Graham, Dr. Wilfrid Hadley, Sir Percival Hartley, Sir Thomas Horder, Dr. Robert Hutchison, Dr. R. A. Rowlands, Dr. Lewis Smith, Dr. Theodore Thompson, Dr. Cecil Wall. The treatment was supervised by Dr. A. C. D. Finzi, Dr. Russell Reynolds, Dr. Gilbert Scott, and Dr. Robert Knox.

FIG. 1.

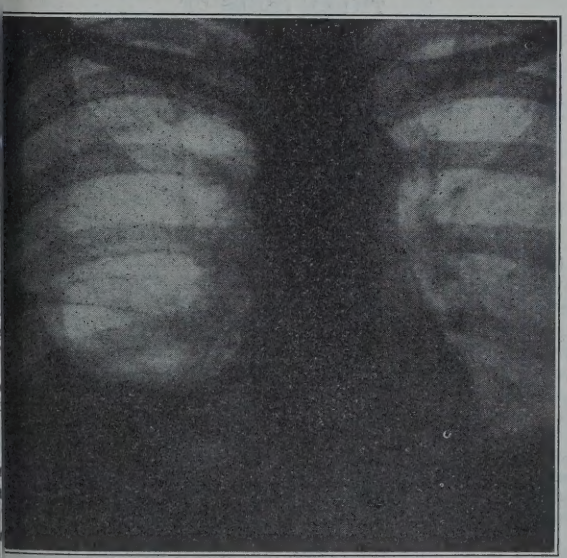


K. L., August 16th, 1923.

Diagnosis.

The diagnosis rests on symptoms, physical signs, adiography, histological examination of secondary eposits, and post-mortem examinations. We have ot attempted to differentiate between primary arcinoma of the lung and primary sarcoma of the ediastinum, partly because of the difficulty of their inical differentiation and partly because, even

FIG. 2.

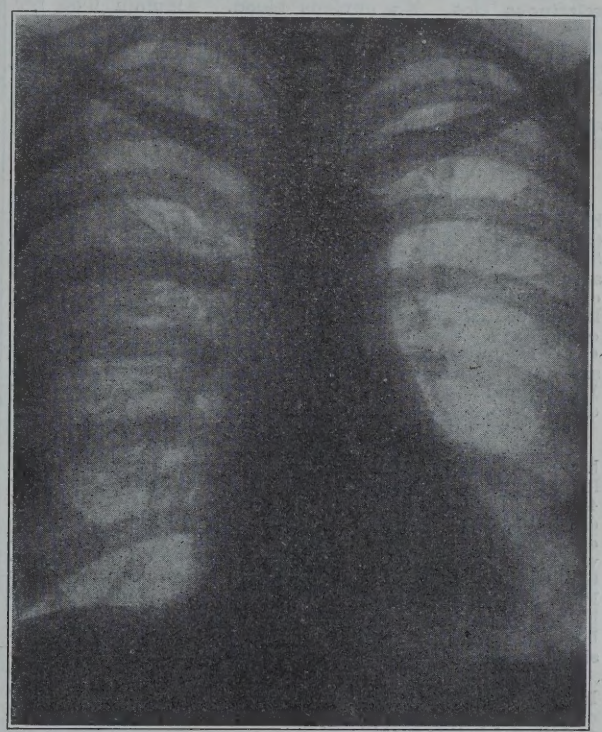


K. L., April 10th, 1924.

stologically, no hard-and-fast differentiation would accepted by all pathologists.

Of the 120 cases investigated, 59 have been treated th X rays, and followed up, either to a fatal mination, or, as with those still alive, to the present te. Of the 59 treated cases, 55 have died, a per-ntage of 93·2. Four cases in the series lived, and these will be reviewed later. The 61 cases which had no X ray treatment all terminated fatally. The average duration of the disease from the first symptom complained of until death was six months for those cases untreated and 11 months for those treated with X rays. The apparent shorter period for those cases untreated is probably fallacious, as many of the cases came to hospital in the last stages of the disease, some only three weeks before death. Moreover, some of the treated cases were of a more chronic type, where symptoms had existed 18 months before treatment was begun. We have no evidence that the treatment caused amelioration of symptoms, except in those cases where the tumour has disappeared temporarily or permanently. In fact, in many cases the symptoms after treatment were aggra-

FIG. 3.



K. L., May 5th, 1925.

vated, malaise or dyspnœa increased, or distressing vomiting was produced.

Review of the Four Cases of Apparent Recovery.

One, George W., aged 31, from the history, course, and X ray appearance would appear to have been a case of fibrosis and probably bronchiectasis of the right upper lobe.

The second, Eliza S., aged 60, was a right upper lobe case with a doubtful diagnosis.

The third, Ernest M., aged 50, was a case with shadowing in the neighbourhood of both lung roots with no certain evidence of malignancy either clinical or radiological.

The fourth case comes into a totally different category and will be described in some detail. All the evidence, clinical, radiological, and histological, pointed almost unequivocally to malignant disease.

Clinical Record.

K. L., aged 25, female, clerk. Admitted to St. Bartholomew's Hospital on August 11th, 1923, under Sir Thomas Horder and Dr. Gow, complaining of shortness of breath.

History of Present Condition.—Five months sore-throat, tired easily, three days later cough, weakness. "Influenza," bed one week. No improvement. Four months pleural effusion (right). Aspirated four times at intervals of three

to two weeks. Six weeks cough with sputum. Three weeks orthopnœa and swelling of left arm. No hæmoptysis. No pain in chest.

Condition on Admission.—Orthopnœic, sallow, face puffy. Temp. 98° F., pulse 130, resp. 40. Pupils equal. Veins at root of neck enlarged, both left and right. Enlarged glands at root of neck, both left and right. No unilateral sweating. No oral sepsis. No pericarditis. Swelling left breast and left arm and prominence to left of manubrium. Signs of bilateral pleural effusion—greater on right. Patch of friction sixth to eighth rib behind on left. Slight œdema of legs. Urine: Nothing abnormal found. Paracentesis thoracis right and left. Two pints removed from each side. Blood count: Dilated veins on left side of abdomen. Other systems: Nil. The radiographic appearance on August 16th is shown in Fig. 1.

Pathological Reports.

August 13th: Red blood cells, 4,180,000; white blood cells, 14,400; Hb., 66 per cent.; colour-index, 0·8.

Pleural Effusion.—4 c.cm. yellowish-green fluid. Large gelatinous clot. No obvious blood. Albumin 0·55 per cent. (Aufrecht). Centrifuged deposit: Lymphocytes 80 per cent.; endothelial cells, 5 per cent.; red blood corpuscles, 15 per cent. No malignant cells seen. Culture: (1) *M. catarrhalis*, (2) staphylococcus.

28th: Section of gland from right supraclavicular fossa; appearances those of endothelial sarcoma such as found in new growths of mediastinum (Sir B. Spilsbury).

Treatment.

X ray treatment under the supervision of Dr. Finzi began on August 24th, 1923. Dose, 4 H. Filter, 0·5 mm. Cu., + 1 mm. Al. 170 K. V. peak discontinous current at 54 cm. and repeated each day for about 12 days (different areas each day). Oct. 5th: Getting worse. Slight bout of fever (Sept. 1st) to 101° irregular for nine days. Neokharsivan. Intravenous 0·3, 0·45, 0·6, and 0·9 g. at intervals of six days. 22nd: X rays repeated. 3 H. Filter, 5 mm. Cu. + 1 mm. Al. at 54 cm. at different areas each day for six days. Nov. 16th: Collosal selenium, three doses of 1 c.cm. and three doses of 3 c.cm. intravenous on alternate days. Dec. 4th: Discharged in statu quo.

Jan. 2nd, 1924: Readmitted for X ray treatment.

Radiologist's Report.—The tumour in the mediastinum has disappeared. Still fluid at both bases. More on right level fourth rib ant. (Dudley Stone). 8th: *X ray treatment.*—4 H. Filter, 0·5 mm. Cu. + 1 mm. Al. 170 K. V. peak discontinuous current at 40 cm. to glands in left side neck, each day for five days (different areas). Went home and was well for ten days, then *neck painful* on movement. Gained in weight. Could walk five miles. March 11th: Pleural friction at angle of left scapula. Percussion dull below this. Friction right base. Fremitus present left base—absent right. 12th: *Radiogram.*—Still fluid on right side but clearer than before. Opacity at left base increased.

Clinical Report.—Lungs same. Abdomen: Dilated veins left side. Liver: Dullness three fingers-breadth below costal margin. Spleen not palpable. Something (?) felt to left and below umbilicus.

April 10th: Radiogram (Fig. 2).

11th: *Blood.*—Red blood cells, 4,050,000; white blood cells, 12,400; Hb., 75 per cent.; C.I., 0·93. Dec. 12th: Radiogram as before. May 5th, 1925: Radiogram. Base both lungs clearer than when last skiagram taken. I should now pass this skiagram as practically normal with the exception of a few dilated bronchi on both sides (Finzi) (Fig. 3).

At the date of writing, March, 1927, Dr. R. Harvey-Williams reports the patient as in perfectly good health and the skiagram is normal.

Discussion.

It may be said that the diagnosis of this case was wrong, and that the histologist was mistaken in his interpretation of the gland section. What are the possible alternatives? Lymphadenoma is the first that suggests itself. It would explain every sign and symptom and the radiographic appearances. The section of the gland did not support this diagnosis; but histologists, like clinicians, are not immune from error. If it were lymphadenoma, the result, in its permanence, is almost as remarkable as if it were sarcoma. Tuberculosis, we think, can be excluded positively. There was no evidence of this, and we doubt if a tuberculous lymphadenitis of the mediastinum has ever produced the huge masses seen in this case. Hydatid or dermoid cyst would not disappear in this manner. A simple inflammatory tumour or tumours is not infrequently the explanation given after the disappearance of an apparent malignant tumour, with or without treatment. In many parts of the body such an interpretation cannot be gainsaid. But what inflammatory mass can be conceived in this situation, giving rise to recurrent bilateral pleural effusion with glands in the neck? Syphilis can scarcely demand serious consideration. There is no record of a W.R., but even if the masses were regarded as syphilitic—which in our opinion would be almost incredible—the whole clinical picture is unlike anything we have seen, heard, or read of in cases of syphilis of the lung or mediastinum.

Conclusions.

1. *Cure.*—One case out of 59 treated by X rays appears to have been cured. All the untreated cases investigated died.

2. *Prolongation of Life.*—Except in the case cured there is no evidence that life was prolonged by treatment.

3. *Amelioration of Symptoms.*—Except in a few cases symptoms do not appear to have been relieved by X ray treatment. Yet it cannot be denied that the psychological effect is great. Whether it should be employed purely as a placebo may be a matter of opinion. Many pathetic letters received in answer to our inquiries showed that a number of the patients died in great suffering, and we feel that there is too great a reluctance on the part of the profession to employ adequate doses of anodyne in painful mortal disease.

4. That one case of apparently definite malignant disease was cured must stimulate further research in this method of treatment. Whether the other remedies combined with the X rays, such as salvarsan and selenium, had an influence is a matter deserving further investigation.

We would express our special indebtedness to Sir Thomas Horder, Dr. Gow, and Dr. Finzi.

Clinical and Laboratory Notes.

THREE CASES OF RUPTURE OF THE UTERUS AT THE SITE OF A PREVIOUS CÆSAREAN SECTION.

BY J. ST. GEORGE WILSON, *M.C.*, M.B., CH.M. LIVERP., F.R.C.S. ENG.,
SURGEON, SAMARITAN HOSPITAL FOR WOMEN; ASSISTANT GYNÆCOLOGICAL AND OBSTETRICAL SURGEON, ROYAL INFIRMARY, LIVERPOOL.

IN the first of these three cases there were definite signs of the onset of labour—viz., dilatation of the external os and the presence of a "show"—though uterine contractions could not be felt. In the second case there was no evidence of the onset of labour, while in the third definite contractions of the uterus were felt together with slight dilatation of the cervix, and a show. The clinical history of the cases was as follows.

CASE 1.—A 3-gravida, aged 27. The first pregnancy had ended in the normal delivery of a living child 5 lb. 4 oz. in weight. The second labour was complicated by a central placenta prævia, and the patient was delivered by Cæsarean section on Nov. 26th, 1923. The puerperium was uneventful.

Pregnant for the third time, the patient was admitted at 6.50 A.M. on July 21st, 1925, and stated that she had come into labour at 5.30 A.M. She was seen by the house surgeon, who did not notice anything abnormal. I saw her at 10 A.M., and she complained of abdominal pain. The abdomen was somewhat distended and distinctly tender. The head of the fœtus could be felt presenting, and was apparently of normal size. On vaginal examination the os was dilated to the size of one finger, and there was a show. As bimanual examination was unsatisfactory, an anæsthetic was administered, and it was then decided that the head would pass the brim successfully. It was noted that one limb of the fœtus lying in front was very plainly palpable, and could be freely

moved about. The presence of the fœtal heart was not definite.

I saw her again at 2.40 P.M., and as the labour had not progressed at all, I decided to remove the fœtus by Cæsarean section. On opening the abdomen, a large quantity of blood was found free in the peritoneal cavity, together with the fœtus and placenta. The uterus was found firmly retracted below and to the left of the fœtus, with a rupture in its anterior wall, throughout the length of the previous incision. I removed the dead fœtus, 8 lb. in weight, and secundines, and as the wall of the uterus appeared thick and healthy I resutured the wound in the wall. At the end of the operation the pulse was good and its rate 122. Convalescence was uneventful.

The interesting point in this case is as to when the uterus had ruptured. If it had ruptured at the onset of labour it is difficult to account for the labour pains. There was no suggestion in the patient's condition of a large hæmorrhage, the only incomprehensible sign being the tenderness and slight distension of the abdomen which suggested a peritoneal crisis.

On Feb. 9th, 1927, this patient reported at the clinic, again pregnant, but uncertain of the period of amenorrhœa. On examination I estimated the duration of pregnancy to be about 26 weeks, and from that date until her admission to hospital on May 5th she was kept under observation. On the 16th, at 5 P.M., she began to have labour pains, and at 6 P.M., by the courtesy of Mr. Leyland Robinson, I did a Cæsarean section. On opening the abdomen there were surprisingly few adhesions, the great omentum being lightly adherent to the fundus of the bladder and low down on the abdominal wall. The previous scar was imperceptible before the uterus was emptied, and had retracted. The placenta was situated on the posterior uterine wall, and the child, a healthy female, weighed 6½ lb.

CASE 2.—A 5-gravida, aged 35. Her first three children had each been delivered by craniotomy. The fourth child had been delivered by Cæsarean section two years previously. During this pregnancy the patient had been under observation at an antenatal clinic, and arrangements had been made for delivery by Cæsarean section about Dec. 23rd, 1925, though the date of expected delivery was Jan. 6th, 1926. On Dec. 12th she complained of abdominal pain and went to bed. At 7 P.M. on Dec. 14th she had severe abdominal pain and vomited. At 9.30 P.M. she was admitted to hospital complaining of severe pain all over the abdomen and between the shoulders.

The house surgeon saw her, and noted that she was very collapsed, that there were no signs of the onset of labour, and that the fœtus was easily palpable. The temperature was 97·6° F., the pulse-rate 96, and the respiration-rate 24. The collapse was treated by hypodermic injections of ether etc., digitalone gr. 1/10, and saline solution 1 pint intravenously. The provisional diagnosis was perforation of the gut.

I was asked to see her on the next day when she had recovered from the collapse. I was struck by her pallor, and the pulse was weak and frequent. The abdomen was somewhat distended, tender, and no fœtal parts were palpable. I was of the opinion that the uterus had ruptured and recommended laparotomy. On opening the abdomen a large quantity of fluid and clotted blood was found free in its cavity. The uterus had ruptured throughout the length of the scar of the previous Cæsarean section; it had expelled the fœtus and placenta and was firmly retracted. The amniotic cavity was unruptured, the fœtus being still enclosed in the sac of membranes and placenta. At one spot the membranes were still attached to the interior of the uterus.

In this instance I did a subtotal hysterectomy after removing the dead fœtus and secundines. At the end of the operation the pulse-rate was 120 and the temperature 97·6° F. One pint of saline was given subcutaneously. On the next day 50 c.cm. of antistreptococcal serum was administered intravenously as a prophylactic, and after that the convalescence proceeded normally, the patient being discharged from hospital on Jan. 11th, 1926.

Microscopical examination of the uterine wall at the site of the wound did not reveal any excessive necrotic change. It showed the presence of a moderate number of polymorphonuclear leucocytes among the muscle-fibres, as well as some chorionic villi. The existence of the latter suggests that the placenta had been situated on the anterior wall of the uterus.

CASE 3.—A 2-gravida, aged 20. The first pregnancy had been terminated prematurely by Cæsarean section on Nov. 18th, 1925, for toxic albuminuria. The patient was desperately ill on admission to hospital, and after reacting slightly to treatment had relapsed; it was believed that she would not stand the strain of parturition. After delivery she had pyrexia up to 100·4°F. on the second and third days, but after that convalescence was normal and uninterrupted. With the second pregnancy she came under observation on Dec. 15th, 1926, with an indefinite history of the last menstrual period having occurred in April, 1926. I estimated the duration of the pregnancy to be about 35 weeks. She had had no trouble, there was no albuminuria, the measurements were normal, and I decided to allow her to attempt delivery normally. She remained in hospital until Jan. 16th, 1927, when she insisted on going out for a day or two. She returned at 5.45 A.M. on Jan. 17th, and stated that she had had severe pain since 5.30 A.M., sudden in onset and situated in the abdomen. The temperature was 97·4°F., the pulse 116 and weak, being at times imperceptible. She was seen by the house surgeon, who noted that contractions of the uterus were perceptible, and that the external os was dilated to the size of one finger. He did not think that the uterus had ruptured at that time, and he gave her morphine gr. 1/4 and digitalin gr. 1/100.

I saw her at 9.45 A.M., when the pulse-rate was 118, the skin was pale, cold, and moist, and the respirations were sighing in character. The abdomen was tender, but fœtal parts could be felt apparently normally, and *the fœtal heart sounds could also be heard.* Laparotomy was performed at 10.15 A.M. There was a large quantity of blood in the peritoneal cavity partially clotted. The great omentum was seen to be lightly adherent to the front of the uterus, round the gaping wound of the rupture, which had taken place through the lower four-fifths of the scar of the previous Cæsarean section. The placenta was seen to be situated on the anterior wall of the uterus over the site of the rupture, consequently it had not completely separated, the amniotic sac was unruptured, and the fœtus was still in utero. I rapidly removed the fœtus, but found it to be dead. Owing to the patient's youth and her desperate condition, I determined to suture the wound in the uterus, and in doing so found that the wall was very thin in its upper part. While hurriedly performing the peritoneal toilette, I collected about 150 c.cm. of blood, and after closing the abdomen by through-and-through silkworm-gut sutures, I transfused her with her own blood, filtered through gauze, followed by 100 c.cm. of normal saline.

On the next day the temperature rose to 100° F., and there was some trouble with the chest. On the three succeeding days the temperature rose to 99° F., and thereafter fell to, and remained at, normal. Convalescence proceeded interruptedly. The "chestiness" cleared up in three or four days.

The points of interest in this case are: (1) The uterus ruptured without expelling the fœtus into the uterine cavity. This, I believe, was due to the fact that the placenta was on the anterior wall and helped to limit the separation of the edges of the rent. (2) The fœtus lived for some hours after rupture took place. (3) In transfusing into a vein, I certainly introduced small clots, and the products of thrombosis of the blood, into her circulation, and I almost expected to produce a generalised thrombosis. At no time, however, was there even a suggestion of pulmonary infarction, though particular attention was paid to the examination of the chest. In this case I propose to excise the thin scar in the uterus before the next pregnancy.

Conclusion.

It is difficult to account for the rupture in these cases. The previous Cæsarean sections had all been done by an experienced surgeon. In no case was there any suggestion of sepsis after the section, not even in the first, which was done as an emergency. In all three of them rupture occurred right at the commencement of labour, there being no question of the scar having to withstand the strain of the expulsive stage; indeed, in the second case there was no clinical evidence of the onset of labour. From this fact one infers that, in cases which are being allowed to go into natural labour after having had a previous Cæsarean section, if the labour starts without rupture of the uterus it can be expected to terminate without risk of rupture. These cases apparently support the dictum, "Once a Cæsarean, always a Cæsarean," to which, however, I do not subscribe, as I see every year a number of cases, delivered per vias naturales, which have previously had Cæsarean sections for conditions which are not present in the

labours in question. The first two cases illustrate the well-known fact that the parturient woman can stand an enormous loss of blood, and also that the uterus tends to empty itself when ruptured, and having done so, retracts efficiently and prevents a further loss of blood both from the placental area and the site of the rupture. In the third case the situation of the placenta on the anterior wall acted mechanically in limiting the separation of the edges of the wound and expulsion of the fœtus and its appendages.

The situation of the placenta on the anterior wall of the uterus under the site of the old scar may predispose to its weakening and rupture. In the second and third cases there was definite evidence of the placental site being in front, and in the first case, in the recent Cæsarean section, when the scar of the previous rupture was found to be sound, the placenta was situated behind.

A CASE OF
PRIMARY ACTINOMYCOSIS OF LUNGS
WITH SECONDARY PERITONITIS.

BY CECIL D. COYLE, M.B., B.CH. N.U.I.,
SENIOR ASSISTANT MEDICAL OFFICER, MILE END HOSPITAL, LONDON.

THE diagnostic difficulties in the following case make it of interest.

The patient, an unmarried girl aged 19 years, was employed as a lamp-shade maker. She had been treated for anæmia four years previously, but had otherwise been fairly strong. There was no history of any chest trouble. Having felt out of sorts for a week, she vomited on Nov. 19th, 1926. The vomiting was followed by pain in the left shoulder, hiccough, and slight hypogastric pain with smarting on micturition. Vomiting and constipation continued until Nov. 23rd, after which the bowels were open daily. On the following day she had a slight rigor. There was no cough or headache at any time.

She was admitted to hospital on Nov. 26th with fever, considerable hypogastric distension, an indefinite lump in the cæcal region, having some overlying rigidity and tenderness, and a similar lump in the left iliac fossa. There was a rough pleural rub and signs of consolidation over the left lower lobe. Per rectum the uterus was found to be normal in size, retroverted and fixed. The number of white cells in the blood was 52,000 per c.mm.; the urine was clear and a blood culture was sterile. While she was under observation her temperature ranged between 100°–103° F., her respiration-rate was about 30, and her pulse slowish. On Dec. 1st a pleural rub appeared at the right base, and a small quantity of slightly turbid fluid was aspirated from the left chest. This fluid remained sterile after prolonged aerobic culture, but contained numerous polymorphonuclear leucocytes. At this time the provisional diagnosis was "primary pneumonia with pneumococcal peritonitis."

On Dec. 4th she had several syncopal attacks and thrombophlebitis of the left axillary vein was noted. The abdominal distension increased in spite of active treatment, and she finally presented the picture of late generalised peritonitis. On Dec. 10th she began for the first time to cough, and brought up a quantity of very foul blood-stained sputum. The cough continued until her death on Dec. 12th, but there was no further expectoration. It is to be regretted that no examination of this sputum was made.

Post-mortem Report.—Moderate emaciation. Diffuse, almost confluent broncho-pneumonia of both lungs with multiple abscess formation. One abscess at the left base perforating the left dome of the diaphragm on to the upper surface of the left lobe of the liver. Pleuræ markedly inflamed and but slightly adherent. One large vegetation on the mitral valve; the heart otherwise apparently normal. Abdomen showed generalised fibrinoplastic peritonitis with left subphrenic abscess (fluid content slight). Scar of healed ulcer in first stage of duodenum. Mass previously felt in right iliac fossa consisted of distended thin-walled cæcum adherent to anterior abdominal wall. Spleen of septicæmic type. Number of small infarcts in kidneys. The remaining organs showed no unusual features.

Microscopical sections of lung, mitral valve, and stomach were prepared and disclosed: broncho-pneumonia with abscesses containing numerous masses of Gram-positive streptothrix morphologically identical with *Streptothrix actinomyces*; acute fibrinous endocarditis of mitral valve with no Gram-positive organisms and very few leucocytes; acute inflammation of serosa of stomach.

The order of events therefore appears to have been: (1) primary actinomycosis of the lungs; (2) perforation of the diaphragm with production of left subphrenic abscess and generalised peritonitis.

I am indebted to Dr. J. I. P. Wilson for permission to publish this note, and to Dr. W. W. Woods, London Hospital, for his kindness in supervising the post-mortem examination.

A CASE OF
PERFORATION OF A GASTRIC ULCER
IN A BOY OF TWELVE.

BY VICTOR P. ROBINSON, B.M., B.CH. OXF.,
HOUSE SURGEON, ROYAL INFIRMARY, SUNDERLAND.

THE following case of perforating gastric ulcer seems worthy of record.

The patient, a delicate, undersized boy of 12, had been previously in the medical wards of the Royal Infirmary, Sunderland, from March 3rd to May 4th, 1927. According to the notes he had complained of pain in the stomach for three months and of vomiting for two months. The pain was of gradual onset, was sharp and stabbing in character, came on about five minutes after food, and lasted for about half an hour. It was felt in the mid-line of the epigastrium and was relieved by pressure. Soon after the onset of pain vomiting came on and relieved it to a varying extent. His bowels acted regularly. He had lost flesh but gained 4 lb. whilst in hospital. On discharge his weight was 4 st. 13 lb. He had no cough, sputum, nor night sweats. He had had diphtheria. On admission nothing had been made out in his chest or abdomen, and his fæces contained no occult blood as shown by the benzidene test. The urine was normal. He was treated in bed on a verandah, and was dieted, first on milk, then on light diet with fish, and finally on full diet on April 22nd, but he still had some pain.

Two days after his discharge on May 4th his pain got worse, and on May 13th, as he was about to get up in the morning, he was seized with sudden severe abdominal pain which doubled him up and caused vomiting. He was brought again to hospital, where I admitted him under the care of Mr. S. Raw, honorary surgeon. The boy looked ill and was suffering severe epigastric pain. His temperature was 99·6° F., the pulse-rate 99, and the respiration-rate 28; his tongue was furred, but his teeth were good; the abdomen was rigid, and its movements restricted, especially in the upper half; respiration was thoracic only. He was tender over the epigastrium but not over the appendix. The abdomen was resonant to percussion, the liver dullness was diminished, but there was no shifting dullness. A diagnosis of ruptured gastric ulcer was made.

At 4.40 P.M. on the same day he was operated upon by Dr. Geoffrey S. Robinson, senior assistant surgeon, under chloroform and ether (1 in 32) anæsthesia, through a right rectus incision. Gas escaped on opening the peritoneal cavity, which contained stomach contents. These were mopped up and a perforation 3/16 in. across was found on the anterior wall of the stomach, half way between the fundus and pylorus and nearer the lesser than the greater curvature. The ulcer itself was thick and more than ½ in. in diameter. The opening was closed and the ulcer infolded by catgut sutures with some difficulty, and a piece of omentum was stitched over the suture line. The abdomen was closed without drainage, the muscles were sutured with chromic catgut, and the skin was united with Michel's clips. For some days there was a discharge from the wound and the boy became very ill with broncho-pneumonia, but this cleared up in ten days after he was placed on an open-air balcony. He gradually improved, put on flesh, and was discharged cured on July 23rd.

I am indebted to Mr. Raw for permission to publish these notes.

THE Sheffield Joint Hospitals Council has under consideration the establishment of a hospital at Sheffield to be occupied entirely by paying patients. It is thought that in a city with a population of half a million there ought to be at least 10,000 people who would desire such a scheme and would be willing to pay an annual subscription of £10 10s.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Continued from p. 557.*)

SECTION OF OPHTHALMOLOGY.

WEDNESDAY, JULY 20TH.

THIS Section met under the presidency of Dr. A. H. H. SINCLAIR (Edinburgh), and the first subject of discussion was

OPTIC NEURITIS.

Prof. HENNING RÖNNE (Copenhagen) said that unfortunately the terms choked disc and optic neuritis were employed in different senses, and (what was worse) with differing meanings, by the ophthalmologist and the neurologist. Choked disc meant the condition in which the swollen disc had attained the arbitrarily fixed minimum elevation of 2 dioptres. The important question was whether the neuritis shown in the disc was in the nature of an œdema, indicating increased intracranial pressure, or was an indication of a local inflammation of the optic nerve. It was not always very easy to decide clinically between (1) a primary papillary œdema with functional disturbance resulting from secondary changes in the nerve-fibres, and (2) a primary lesion of the optic nerve with secondary papillary œdema. Behr had endeavoured to introduce a special term for genuine papillary inflammation—namely, papillitis—and to distinguish ophthalmoscopically between papillary œdema and papillary inflammation, but Prof. Rönne thought it impossible to maintain this distinction, for, as a matter of fact, if there was papillitis there was œdema, whatever the producing cause might be. When the inflammation in the optic nerve was situated very far forwards and involved the papilla, there was sure to be roundcelled infiltration within the eyeball with opacities in the vitreous humour.

The term "retrobulbar neuritis," said Prof. Rönne, as a clinical expression for a group of diseases in which either there might be no changes in the disc recognisable with the ophthalmoscope, or there might be changes of varying degree, even to the extent of choking of the disc. The most important clinical feature common to the group was the central scotoma. Between the two extremes there were links which showed that they could not be of altogether different origin, and it was a notable fact that in disseminated sclerosis either type might be present. Typical cases of retrobulbar neuritis might show choked disc, the orbital pains might be absent, the tendency to spontaneous improvement might not be evident—e.g., in Leber's atrophy—and areas beyond the macula might be involved, so that it was impossible to depend on any one symptom or sign for purposes of classification. Of great interest was the condition of the medullary sheath. In disseminated sclerosis the sheath was often destroyed, leaving the axis-cylinder naked, and perhaps this might be considered a feature of the entire group; it was certainly present in some cases of diabetic amblyopia. It had been suggested that this might be the real characteristic of the group—namely, that by virtue of a selective action the macular fibres were more susceptible of the loss of their sheath than the peripheral fibres.

Having thus reviewed the three clinical types—papillary œdema, optic neuritis, and retrobulbar neuritis—Prof. Rönne turned to a group not coming strictly under any of these clinical headings—namely, choked disc with sudden initial blindness. This type, he said, was very imperfectly noticed in the literature, and in such a condition the questions obviously arose: Was the sudden loss of sight a direct consequence of the choked disc; or were the two set up, relatively independently, by the same cause; or was the choked disc a consequence of the vision-destroying lesion? He was inclined to accept the last of these explanations. He found as a cause of the blindness a conspicuous plaque, of degenerative nature, arising from complete destruction of the medullary sheath, the place of which was filled with fatty and granular cells. Such plaques might even be present in the chiasma, destroying both optic nerves, and were also to be found in cases of pseudo-tumour with myelitis. Changes in this plaque-formation made it possible to account for those singular cases in which a central scotoma might change into a bitemporal hemianopsia. It was unnecessary to assume that a plaque once formed meant a permanent and distinctive lesion; recovery and resumption of function were not excluded. In the examination of fields, which thus varied from one point to another, Prof. Rönne advocated a movement of the test object along a line at right angles to the edge of the scotoma or blind area, irrespective of the customary circles or radii.

Dr. J. V. PATERSON (Edinburgh) said that the observer should not allow himself to be hidebound by rigid terms such as optic neuritis and choked disc. It was evident that there was a class of cases in which the essential feature was not one precise ophthalmoscopic picture, but the existence of intracranial pressure. In such cases the readings obtained with the Gullstrand ophthalmoscope promised to be of great assistance, and careful investigation must be made of any visual disturbance and of radiograms. For such a group of cases Traquair considered that the term "plerocephalic œdema" should be adopted. Exactly how the œdema produced the ophthalmoscopic picture was not very easy to explain, but apparently the old theory that there was some irritant or toxic substance in the fluid had fallen into disrepute, and indeed the improvement obtained by trephining, and the completeness of the recovery which might result, seemed to negative it. He reminded the meeting of the readiness with which an œdema may come on in the eye, as, for example, the chemosis seen when hordeolum was coming on in the adult. He thought that an analogous condition might explain some of the transitory appearances.

Dr. Paterson quoted with approval Behr's description of the fundus in the retrobulbar type of neuritis, but remarked that it was well nigh impossible to make any differentiation of type by the ophthalmoscopic appearance alone, and these cases certainly did not form a group so clearly outlined clinically as the plerocephalic series. They might be classified, however, into certain subgroups, of which two were of more importance than the rest: (1) A small group in which inflammation of the nerve had spread by contiguity; in these cases the periphery of the field seemed to be involved rather than the centre, and among them were cases of optic atrophy in children with a positive Wassermann. (2) A large group due to toxins circulating in the blood; in some of these cases the nerve head exhibited definite changes, if the focus was near to the globe. Usually one eye only was affected, and there was a strong tendency to complete or nearly complete recovery. He expressed himself as very sceptical of the alleged close and frequent relation between disease of the nasal sinuses and retrobulbar neuritis; his experience gave little or no confirmation of such a view, though he did not deny that such a relation might exist. The ophthalmic surgeon faced with a case of retrobulbar neuritis might often feel called upon to invoke the assistance of the rhinologist, but among all his cases of nasal disease did the rhinologist ever find his patients complaining of loss of sight?

There were also certain other minor groups, besides those of diabetic and tobacco amblyopia, which were not included in the subject under debate.

Dr. A. J. BALLANTYNE (Glasgow) said that the consultant ophthalmic surgeon had chiefly to deal with (*a*) papillœdema connected with intracranial tumour, meningitis and other central disease, and (*b*) the optic neuritis or neuroretinitis of renal disease. Often the earlier stages might be unobserved, for there were no visual disturbances to call attention to the eye. It was impossible altogether to distinguish between optic neuritis and choked disc with

prominence of the disc amounting to 1·5 dioptres or more, because such an œdema must have passed through an earlier stage indistinguishable from optic neuritis; in any given case of this type an apparent optic neuritis might be a choked disc in its early stage. He deprecated too ready acceptance of clinical records of recovery of vision in retrobulbar neuritis after operations—e.g., on the nose—as such cases had a tendency to recover spontaneously, and false conclusions might readily be drawn from the history. He was in favour of a conservative attitude in regard to operating; possibly in some cases the benefit after operation had been due merely to local blood-letting, ventilation, or to the use of adrenalin. He would certainly not be disposed to resort to operative treatment until six weeks had been spent in milder measures. After describing a number of cases under his care, Dr. Ballantyne concluded by saying that when choked disc occurred after fracture of the skull it was often attributed to hæmorrhage into the sheath of the nerve, but he had one case in which this could not possibly be the explanation, since the patient had retained excellent macular vision.

Prof. VAN DER HOEVE (Leyden) thought it not altogether disadvantageous to have the two names, choked disc and optic neuritis, but said it was a pity when they were confused, and employed without sufficient attempt at precision. Uhthoff's rule of swelling to an extent of 2 dioptres was not meant to be read too rigidly. He thought that operation in cases of choked disc was best done when vision was just beginning to fail, and inasmuch as it was never possible to be absolutely certain of the diagnosis, it was wise to operate, as otherwise blindness was certain, though the patient might live a long time. He did not advise operation when there was choked disc with sudden initial blindness. In all head cases the coöperation of radiologist with neurologist (or rhinologist) and ophthalmic surgeon was essential, and the last-named ought to be as familiar as possible with X ray photographs of the skull. By employing the ophthalmoscope during the operation Prof. van der Hoeve had satisfied himself that it was the opening of the dura which was the essential point in relieving the pressure-œdema. He agreed that the relation between retrobulbar neuritis and the nose was real, but thought that its importance was greatly exaggerated.

Dr. H. M. TRAQUAIR (Edinburgh) said that it was unjustifiable to use a term ending in "itis" unless it was certain that actual inflammation was present. He preferred the term "plerocephalic œdema" for a large proportion of the cases with choked disc. He rather thought that the central scotoma after hæmorrhage was not a true retrobulbar neuritis, but a toxic effect due to the hæmorrhage. Tabetic atrophy he suspected of being a form of neuritis.

Dr. GEORGE YOUNG (Colchester) described a case in which choked disc appeared within a few hours after a head injury which had produced a large intracranial hæmorrhage. The patient was promptly trephined, the hæmorrhage was stopped, the blood-clot was removed, and the result was complete recovery.

Sir JOHN PARSONS (London) regarded Prof. Rönne's explanation of the occurrence of plaques in disseminated sclerosis as very important.

Dr. G. E. DE SCHWEINITZ (Philadelphia, U.S.A.) laid down two rules in regard to operation in choked disc—viz., that time must be taken to make a thorough conservative investigation of all the facts, and that when any interference with vision could be discovered (e.g., enlargement of the blind spot) by refined methods, operation should be promptly performed. At a late stage operation did no good visually, though it might be required for the relief of pain.

Prof. W. H. WILMER (Baltimore, U.S.A.) had seen cases in which opening up of the sinuses had given great improvement in cases of central scotoma with neuritis, but if it was to be of service the operation must open up the cells immediately surrounding the nerve canal.

Prof. W. H. WILDER (Chicago, U.S.A.) agreed with Dr. Paterson about the transitory œdema in the neighbourhood of a focus of inflammation, and thought that Prof. Rönne's plaques might be of the nature of some such pre-inflammatory change.

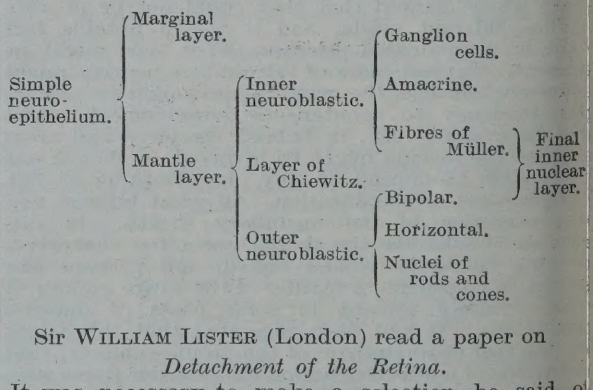
THURSDAY, JULY 21ST.

At the second session of the Section Miss IDA MANN (London) read a paper on the

Comparative Development of the Retina.

Her paper dealt mainly with two aspects of the process of differentiation in the developing vertebrate retina. In the first place, it was shown that there is a definite sequence of events in the development of the retina, which holds good in any animal of the vertebrate type so far examined. In the second place, attention was drawn to the rather curious mode of development of the amacrine cells, which empirically show very close connexion with the ganglion cells, though in the adult state they are much more intimately associated with the bipolar cells. The retina, said Miss Mann, is evolved from the simple neuro-epithelium of the optic cup by a process of separation of the nuclei into layers. At first only one layer of nuclei can be recognised. Very early, however, two zones, an inner and an outer neuroblastic layer, become visible, separated by an interval, the transient fibre layer of Chiewitz. From the inner neuroblastic layer are differentiated the ganglion cells, the amacrine cells, and the nuclei of the fibres of Müller. From the outer neuroblastic layer come the nucleus of the bipolar cells, the horizontal cells, and the nuclei of the rods and cones. The final stage is reached by the disappearance of the transient fibre layer of Chiewitz and the consequent blending of the amacrine and Müllerian fibre nuclei with the bipolars to form a definite inner nuclear layer. The transient existence of the amacrine cells as a separate layer is most marked in birds and in the fovea centralis in man, though it may also be present in other vertebrates. When marked, it is possibly associated with a final high grade of functional activity. Only in birds is the same height of development reached as in man, but in the birds this development is over a large area, whereas in man the process reaches its height in the macula only.

The following diagram was shown to illustrate the development of the retina:—



Sir WILLIAM LISTER (London) read a paper on

Detachment of the Retina.

It was necessary to make a selection, he said, of those cases of simple detachment which were suitable for treatment. Certain cases gave a reasonable chance of success; others gave none. When both eyes were affected, or when there was only one seeing eye, there was probably no reasonable chance of success, and it was best to mark time, to make the patient feel that everything was being done, and to employ rest in bed, bandages, &c. It was on the question of treatment in cases of detachment occurring in one eye only that there seemed to be divergent views. In spite of articles in the press claiming successes amounting to 100 per cent. the real prospect of restoring sight was very slight. Only those cases in which there was reasonable chance of success

ould be subjected to operative treatment. Unsuccssful treatment meant not only monetary loss to e patient, but loss of prestige to the operator and s profession. Some surgeons frankly stated that e condition was hopeless; some never advised ything beyond rest, which might consist of lying wn for 20 minutes, or of complete rest with the ad never lifted from the pillow for weeks. The ajority, he imagined, advised rest, constitutional eatment, and counter-irritation, and if these were successful, then resorted to operation. He had ason to think that a large number of cases were eated on a purely routine plan without any endeavour find the cause in the individual case; but sometnes it was possible at least to make a reasonable ess at the reasons for detachment. The detached tina had either been pushed off the choroid from thout or dragged in from within or floated off through hole in the retina. When it was dragged in by atricial bands in the retina itself, operative treatent could be of no avail, but if the bands were rmed in the vitreous, it was not impossible that nefit might result from their division. There peared to be a general consensus of opinion that nen holes were present operative treatment was ntra-indicated, and that had been the conclusion a committee of the Ophthalmological Society 916). It was, then, of vital importance before ciding upon operation to be satisfied that no hole isted. As a matter of fact, however, careful examition would not show a hole in an invisible part of e fundus. The retina at the edge of the hole was vays rolled inwards on itself, and often showed stic degeneration—so much so that the existence a hole had been attributed to the rupture of one of ese cysts. Round it the vitreous was often someiat denser; at points there might be a firmer achment than was normal between retina and oroid. When the surgeon was confronted with a se giving no obvious clue to the actual cause of the achment, and with nothing definitely to contralicate operation, it was best to spend a fortnight such measures as rest in bed, absorptive treatnt, counter-irritation, and subconjunctival injecns. If these failed, operation should be done. e treatment ought to be thoroughly and sufficiently ried out, and the patient should have no reason to l that he had missed any fair chance that operation other measures might have afforded him.

Dr. W. CLARK SOUTER (Aberdeen) read a paper on

Spontaneous Reattachment of Detached Retina.

er giving short notes of six recent cases (two umatic, two idiopathic, one myopic, one during gnancy) in which a gross detachment of retina l apparently disappeared, leaving choroidoretinal ophy-like changes in three cases, retinitis striata two, and an apparently normal fundus in one e, Dr. Souter discussed the pathological findings published cases in which reattached retinæ had ne to the microscope, special mention being made the cases of Rönne and Klainguti. In one of his es of retinitis striata—an idiopathic one—watched r 17 years, the long white band at the edge of the ttached area was crossed by vessels which were iously not retinal, and not likely to be choroidal, rather like new vessels. They had a strong emblance to, and offered a possible explanation of, se cases described by Sir William Lister in the *thalmic Review* for 1903 under the heading Angioid eaks of the Retina.

Dr. R. A. KERRY (Montreal) was convinced that rtain cases injection of iodide had been of immee and permanent value.

Mr. INGLIS POLLOCK (Glasgow) read the reports of cases of detached retina in which recovery urred after operation. In the first case there was elapse, and although the patient had to wait six ths for readmission to the infirmary, the operai was successful in restoring the retina to its nal situation; that was seven years ago, since n there had been no recurrence. In the second case—a traumatic one in a myope of 9 dioptres—one operation sufficed, and the patient had had no recurrence since it was performed six months before. Both cases showed that there was no improvement until the inter-retinal fluid was withdrawn; in fact, both patients became worse while they lay at home with both eyes bandaged, and the first showed the success of the operation in spite of the recurrence of the detachment. Mr. Pollock further said that he had seen a small detachment cured by operation, followed by recurrence of the detachment and subsequent complete loss of sight in the eye by the extension of the detachment all over the fundus.

Sir ARNOLD LAWSON (London) told of spontaneous reattachment in two apparently hopeless cases. The first was that of a woman with changes in the fundus and vitreous, chronic colitis, and neurasthenia. A few months ago she acquired a very large shallow detachment of the retina below. She would not rest in bed—"it was like trying to keep a pea in a frying pan"—and was quite an unfit subject for an operation. Some time later she returned saying she had recovered her sight. The detachment had entirely gone, and so far there had been no signs of any recurrence. The other case was that of a lady of 70, very stout and plethoric, who had an enormous black "umbrella" detachment, due no doubt to hæmorrhage. She scoffed at the idea of remaining in bed. In reply to a question as to her other eye, she was told that it was in no special danger, but that she must be careful not to hustle or overexert herself in any way, and to avoid stooping. As the second eye was sound she determined to have no treatment. Some time later, anxious to meet her daughter at a station, she ran up the hill, arrived at the top all hot and breathless, and remarked to her daughter, "Good gracious, I can see!" The retina was found to be in position, and had remained so.

A short discussion followed, after which Sir ARNOLD LAWSON read a paper on the value of

Antiseptics in Modern Ophthalmic Surgery.

There were, he said, three obvious sources of infection in ophthalmic surgery. The first was from contamination of the conjunctival sac. The second was from instruments and dressings; and in this matter too much care could not be taken. The third was from the surgeon's fingers. In Sir Arnold Lawson's opinion gloves interfered so seriously with the sense of touch that they could not be used; but since the hands could never be made strictly sterile, great precautions must be taken to prevent contact with the business part of any instrument or suture. In the event of any such accident the immediate use of flavine (1 in 1000) was to be relied on as efficient and yet not irritant; it had, however, no power of penetration. He considered that it did not delay healing, even when used daily in a strength of 1 in 4000. It was useful, too, as well as protargol, when the lash region and the ciliary margins were not entirely healthy. He had great faith in hydrogen peroxide when it was necessary to take risks and operate in presence of a septic condition of the eye.

Dr. H. M. TRAQUAIR (Edinburgh) read a paper on the

Incidence of Tobacco Amblyopia in Edinburgh and District.

Cases of this condition, he said, had been found to be about 1 per cent. of the out-patient cases during a number of years. Four male and one female patients had contracted the disease from cigarette-smoking. By comparing the curve of frequency of tobacco amblyopia with that of arrests for drunkenness, he showed that there was no similarity in the incidence, and this made it very improbable that alcohol was in any degree the underlying cause, as was sometimes believed. Furthermore, the Edinburgh patients with tobacco amblyopia were almost entirely of the respectable working class. He related the cases of three persons who had become blind from drinking methylated spirit, in one of which a man of 40 actually drank a pint a day for four months

before symptoms came on. No case of tobacco amblyopia ever proceeded to complete blindness, and an interesting feature was that vision sometimes became worse for a time after smoking had stopped. There was very often some precipitating cause, whether physical or psychical; and though the amblyopia was never unilateral, there were indications that one eye might be affected rather earlier and perhaps more deeply than the other.

Prof. VAN DER HOEVE stated that he never saw cases of tobacco amblyopia in Holland; he did not believe that it ever occurred, but he could not tell why.

Dr. DE SCHWEINITZ said that he himself had never seen a toxic amblyopia of this particular type in a drinker who was not a smoker, and only two cases in smokers who were absolutely teetotal.

Dr. F. H. DIGGLE (Manchester) read a paper, chiefly statistical, dealing with the relationship (or rather non-relationship) between nasal disease and lacrymal obstruction.

The PRESIDENT (Dr. SINCLAIR) performed before members of the Section his special operation of extraction of cataract in the capsule.

SECTION OF RADIOLOGY.

WEDNESDAY, JULY 20TH.

THIS Section met under the presidency of Dr. J. M. WOODBURN MORISON (Edinburgh) and the subject first discussed was

X RAYS IN THE DIAGNOSIS OF INTRATHORACIC GROWTH.

Dr. STANLEY MELVILLE (London) pointed out that in pre-radiological days there were but few publications dealing with intrathoracic neoplasms, and such as there were dealt with the matter only from the standpoint of morbid anatomy. Out of 74 cases reported in 1904 by Sehrt, in six only had a correct clinical diagnosis been made. Our forebears could go no further as regards the diagnosis than the symptom-complex of increased intrathoracic pressure. Intrathoracic new growths were believed to be very rare and the prognosis was considered hopeless.

It was customary to classify intrathoracic new growths as benign and malignant, but only in the pathological sense. Dr. Melville asked if this distinction could be drawn, for every intrathoracic new growth, however benign, must in time kill the patient by pressure. This fact must be appreciated by clinician and radiologist on account of the vital necessity of early diagnosis. Unfortunately, even true malignant neoplasms had an insidious onset and grew to a considerable size before causing dyspnœa from pressure. He considered that, on the first evidence of even occasional breathlessness which could not be accounted for, radiological examination was indicated.

Benign Neoplasms.

Benign neoplasms were for the most part extra-pulmonary.

Fibromata gave rise to rounded, well-defined opacities springing from the posterior thoracic wall and pushing forward the lung rather than invading it. Owing to the non-irritant structure of the growth there was seldom any pleural adhesion, and diagnosis was rendered easy by the production of an artificial pneumothorax. When this was done an isolated free tumour which was extra-pulmonary could be made out. This procedure was of great value in the differential diagnosis between fibroma and fibro-sarcoma.

Teratomata occurring in the thorax were generally of the dermoid type, of epiblastic origin, and containing any of the constituents of skin and its appendages. Growing from the third branchial cleft or the remains of the thymus, they were anterior in position in contra-distinction to the fibromata. Dr. Melville had seen as many as five dermoid cysts at the Brompton Hospital in the last 12 months. The most important point in the radiological diagnosis was the examination in the dead lateral plane, when the tumour was seen to lie anteriorly close to the sternum, being fairly well-defined, but often markedly irregular.

Malignant Neoplasms.

Dr. Melville quoted statistics of pulmonary carcinoma from the year 1886 to the present day, and pointed out the apparent increase in the incidence of this disease in all countries. He questioned the real existence of primary sarcoma of the lung, as opposed to lympho-sarcoma arising from the mediastinal glands and, therefore, primarily mediastinal. Metastasis from some undiscovered primary focus, such as the prostate, might account for some of the recorded cases.

Finally, he discussed mediastinal new growths, laying stress on the difficulty of the differential diagnosis from aneurysm of the thoracic aorta. If the condition had persisted for 18 months or more aneurysm was the more probable. The diagnosis might depend on the occurrence of erosion of bony structures which seldom occurs in mediastinal sarcoma. He concluded his paper by inviting discussion on the question, Is the increase in the incidence of primary pulmonary carcinoma real, or is it possible that many of the cases now recognised as carcinoma were previously mistaken for pulmonary tuberculosis, especially of the fibroid type?

Discussion.

Dr. THURSTAN HOLLAND (Liverpool) said that he did not believe that the increase in the incidence of primary pulmonary carcinoma shown in the statistics was a real one. He attributed it to more accurate diagnosis. Discussing the differential diagnosis of mediastinal new growth and aortic aneurysm, he laid great stress on the observation of a definite expansile wave-like pulsation passing along the margin of the shadow; this appearance he regarded as pathognomonic of aneurysm.

Dr. A. E. BARCLAY (Manchester) thought the time had come when the text-books of clinical medicine should be revised in the light of radiological knowledge. As an example, he mentioned the physical sign known as tracheal tugging, which was so much stressed as a sign of aneurysm in the books. He had failed to elicit it in a large number of cases in which he had proved, by X ray examination, the presence of an aneurysm of the arch.

Sir HUMPHRY ROLLESTON (Cambridge) said that he regarded tracheal tugging as a sign which was of value.

Lord DAWSON OF PENN thought that the radiologist should take a greater part in the teaching of clinical medicine. He suggested that in cases in which the radiological examination was an important factor in the diagnosis, the radiologist might with advantage discuss it, and the conclusions to be drawn from it, before the students, immediately after the demonstration and discussion of the case by the teacher of clinical medicine.

The PRESIDENT then described the system of undergraduate instruction in radiology in force at Edinburgh University, and the discussion was continued by Dr. N. S. FINZI (London), Dr. CAMPBELL SUTTIE (Glasgow), Dr. ROWDEN (Leeds).

In his reply, Dr. MELVILLE said that he placed no reliance on the presence or absence of pulsation in the differential diagnosis of aneurysm. A tumour might show violent transmitted pulsation, while an aneurysm with thickened, calcareous walls might show none.

The second discussion of the Section was presided over by Dr. R. E. ROBERTS (Liverpool), the subject being

X RAYS AND RADIUM IN THE TREATMENT OF CARCINOMA OF THE BREAST.

Dr. N. S. FINZI (London) said that it was generally agreed that cancer started as a local disease, or at any rate a local manifestation. Generally it tended

ooner or later to spread, at first by the lymphatics nd later, in some cases, by the blood stream. If he disease was completely removed while still local, vhether by surgery or by irradiation, the patient vould be cured. If, however, it had spread beyond he area removed, or beyond the area to which a ufficiency of irradiation has been given, growth ecommenced. Consideration of the lymphatic lrainage of the breast showed that when the primary rowth was in the outer part of the breast further rouble might be expected first in the axillary and ubclavicular glands and later in the supraclavicular lands and posterior mediastinum. If the growth vas in the inner part of the breast, the inner end of he intercostal spaces and the anterior mediastinum vere the danger zones. If it was in the upper part f the breast the supraclavicular glands were to be uspected. In advanced cases the disease often nvaded the pleura, possibly by the sternal or inter-ostal glands, possibly by way of the mediastinum. he cells would eventually reach the blood stream y the thoracic duct. Involvement of the mediastinal, racheal, and bronchial glands might often be dis-overed by a skiagram, as also pleural metastasis and lood-disseminated metastases in the lungs. They ould not be seen in the early stage, being only visible hen in the form of definite tumours. Skiagrams, oth anterior and antero-lateral, should be taken of very breast carcinoma for X ray treatment.

Radium Rays and X Rays.

The low penetrating power of the α rays made hem of no importance in therapy. The same remark pplied in a large degree also to the β rays, much etter results having been obtained by γ and X rays. t was found that there was a certain minimal dose hich would inevitably prevent the development of xperimental growths. This was the so-called lethal ose, and would cause the growth to be absorbed by he tissues of an animal into which it was implanted, nd would then immunise the animal against future nplantation of similar growth. Larger doses would qually prevent the development of the graft, but ould not immunise to the same degree, and when bout 20 times the lethal dose had been given the raft no longer immunised. Sublethal doses reduced ne ratio of successful implantations without in every ase preventing them. The lethal dose was much igher than could be applied to the living tissues ithout causing necrosis. In the human being in eneral the more rapidly growing the neoplasm the ore rapidly would it succumb to irradiation. But s rapidly growing tumours spread more quickly, wider area and more distant glands would need to e treated, and a greater number of cases would ow distant metastasis. With rapidly growing mours the effect of the rays was seen quickly—1 a day or two—whereas with the more slowly rowing forms changes might not appear for some eeks. As the wave-length of X rays decreased o their effects took longer to appear.

The γ rays produced an effect in about the same me as X rays produced by 150 k.v. continuous rrent. Dr. Finzi believed that the response to rays of carcinomata and epitheliomata was better ne higher the wave-length, if full doses were given. onsequently γ rays were the best if applied in fficient quantity. Lymphosarcoma, however, prob-bly responded at least as well to medium wave-ngths. X rays could easily be obtained in large uantities; on the other hand, radium could con-eniently be applied for prolonged periods. In the re instances in which large quantities of radium ould be secured they were not concentrated into a oint focus, but spread over a large radiating surface o that the relative depth was much increased. Radium ys were more penetrating, and for the same amount f damage to healthy tissues, exerted more effect on arcinomata than X rays. The disadvantage was at the underlying lung must get a large dose and bsequent damage was likely. On the other hand, ith X rays the use of the glancing method would largely prevent this. Radium was also used by burying a number of radium containers in the tissues; usually hollow needles containing either radium salt or radon were employed. The needles were used deep to the growth if possible, or in its deeper layers, the gland areas being needled at the same time. Dr. Finzi had the impression that the results with buried radium were better than the external methods, provided the wounds remained aseptic. This could only be accomplished by meticulous care owing to the devitalising effect of the irradiation upon the tissues.

Treatment.

Dr. Finzi discussed the actual treatment of cases under the following headings, speaking first of treatment by irradiation alone.

(1) *Primary growth localised in breast; no palpable glands.*—In an operable case without contra-indications for surgery, irradiation should not be used unless the breast was to be subsequently removed, but the loss of time, possibly of two months, involved in preoperative irradiation was probably more than compensated for by the diminished likelihood of insemination of the growth at operation. In many cases it had been possible to render inoperable growths inactive for long periods by X rays, but their complete disappearance had been rare. The results with radium had been more encouraging.

(2) *Primary growth in breast; palpable glands in axilla.*—Treatment by irradiation largely depended on the radiographic appearances. If mediastinal involvement was seen, nothing but mediastinal treatment was of any value, and as this usually prevented efficient doses being given to the breast and axilla, the question of surgical help must be considered. If the mediastinum did not appear to be involved the breast should be treated as if operable, and the subclavicular and supraclavicular regions must be irradiated. If the mediastinum was subsequently found to be involved it could be treated with X rays.

(3) *Primary growths with supraclavicular deposits on the same side* must always be regarded as affecting the mediastinum, and unless mediastinal treatment could be adopted with correct dosage of the breast, axilla, and supraclavicular regions with X rays, no permanent success was possible. Combined radium and X ray treatment might be useful.

(4) *With definite mediastinal involvement.*—Until recently Dr. Finzi said he had regarded cases with definite mediastinal involvement as almost hopeless. Recently, however, several cases had done extraordinarily well. It was more than three years since his first case had been treated by his present technique and the patient was still well.

(5) *Treatment of distant metastases.*—Bone metastases were usually very painful and there might for a time be only one or two. Treatment gave so much relief that it could not be refused, even although it was certain that the patient would ultimately succumb to other metastases.

The general lines of treatment for local recurrence after operation were similar to those for a primary growth. With distant recurrence in the axilla and coracoid region and mediastinum, the treatment would be the same as when the primary growth was present. Distant metastases must be dealt with on their merits, but they were worth treating on account of the great relief from pain, lasting for many months, which could often be given.

With regard to post-operative prophylactic treatment, Dr. Finzi held that the methods used should be exactly the same as when there was a demonstrable recurrence and the doses should be just as full. The assumption was that some disease still remained and the most thorough methods should be used to eradicate it.

After-Effects of Irradiation.

Immediately after treatment some patients suffer from sickness which might be considerable; this could be much diminished or even abolished by certain precautions. Spreading of the treatment over several

days was effective and the good ventilation of and exclusion of all corona discharge from the treatment room was important. The administration of gr. x. of chloretone before the treatment, and three times a day during it, was also of use.

After describing the effects of excessive irradiation of the skin, Dr. Finzi explained that when effective doses were used on the chest wall it was difficult to prevent the lung from receiving large doses. Many such cases would later develop a characteristic lesion of the lungs. It did not occur in all cases unless the dose had been very large. The acute form produced by a large dose of irradiation within a few days showed itself first as a pneumonic patch in the lung; later the typical radiographic appearances of bronchiectasis developed, generally, however, without the symptoms of that condition. In the chronic form caused by irradiation at intervals over a long period, the changes were similar, except that the pneumonic stage was not observed. In the final stage the patient was usually unconscious of any abnormality, but in one acute case a typical bronchiectasis remained.

Technique and Results.

Technique was discussed with special reference to the glancing methods devised by Dr. Finzi and also by Holfelder of Frankfurt. Dr. Finzi said that he used continuous high-tension current at 170 to 185 k.v. Radium might be given by needling, or by external applications in which the radium is supported at a distance of some 3 cm. from the surface of the skin, tubes being distributed at intervals over moulds of special wax or a splint of thin celluloid or wood.

Discussing results, Dr. Finzi said that palliation and prolongation of life were the rule, cure the exception; but undoubtedly the radiologist ought to get the patient at an earlier stage than was the rule at present. The use of radium needling followed by extirpation, if desired, in earlier cases, seemed to offer a better chance of cure than operation with subsequent irradiation; but prophylactic irradiation was not to be withheld if operation was preferred.

Discussion.

Dr. DOUGLAS WEBSTER (London) said it was no longer true that the only chance for the patient with cancer of the breast was early operation. Some radiologists had now had results similar to those of irradiation treatment of cancer of the cervix—namely, cures in a certain percentage of inoperable cases, and results in operable cases equal to or better than those of operation. He thought the mortality from cancer was more likely to be lowered by an extension of radiological methods than by any other means known at present. Owing to the natural repugnance to operation felt by most patients, and their delay in admitting that they had a lump in the breast because they had no pain and feared that an operation would be forced on them, a large proportion of patients came first under observation at a late or too late stage. Patients would report earlier if they knew there was an alternative treatment to operation. Operation in a very considerable percentage of cases was incomplete, as nearly a third of the post-operative irradiation series had shown small early recurrences, most of which disappeared with further irradiation. A considerable number of rapidly recurring cases had been met with, which appeared to confirm clinically the experimental observation that the best way to make an animal tumour grow was to cut into it. Because of the deaths of so many of these recurrent patients preoperative irradiation was strongly advocated, to sterilise the tumour and its lymphatic drainage areas before operation. The surgery of cancer in this sense was in a pre-Listerian stage, because of the incalculable risk in any given case of dissemination of active tumour cells and local recurrences. Dr. Webster gave statistics from 512 cases of breast cancer treated by X rays and radium, showing the proportion of successes and failures met with in recurrent, prophylactic (post-operative), and primary cases treated. In his view in breast cancer, as already in rodent ulcer and in cancer of the cervix and tongue, irradiation was tending to become the primary, and surgery the secondary, method of treatment.

Dr. M. R. J. HAYES (Dublin) then described his results, exhibiting large diagrams showing the result of treatment of carcinomata at various stages.

Dr. A. E. BARCLAY (Manchester) doubted whether the results of X ray treatment with the high voltage now available were in any degree better than were obtained years ago with what was termed medium voltage therapy.

Dr. R. E. ROBERTS took a gloomy view of the results of the X ray treatment of breast carcinomata.

The PRESIDENT asked of those irradiating any malignant growth the question—What exactly are you hoping to do to the tumour? If it was hoped for complete destruction of all the malignant cells that was a physical impossibility. He could show a section of a heavily irradiated malignant growth in which, side by side with cells so completely destroyed as to show calcification, were others which were still actively growing.

SECTION OF MENTAL DISEASES.

WEDNESDAY, JULY 20TH.

WE have already reported (THE LANCET, August 6th p. 277) a meeting of this Section held in conjunction with the Royal Medico-Psychological Association. Another joint meeting with the Association was held on July 20th, under the presidency of Dr. HAMILTON MARR, when the subject of discussion was

CHRONIC SEPSIS AS A CAUSE OF MENTAL DISORDERS.

Dr. WILLIAM HUNTER (London) said that the mental conditions chiefly aggravated or caused by sepsis were dementia præcox, manic-depressive insanity, paranoid conditions, psychoneuroses, and the toxic insanities. He had made a special appeal for the study of focal sepsis in 1900, and after 20 years a response had come in the energetic work of Dr. H. A. Cotton, of the New Jersey State Hospital, in 1923.[1] Since then more and more attention had been paid to the subject in this country.

Surgical sepsis was generally an obvious complication with easily recognisable lesions, caused by only two or three kinds of organism. Medical sepsis was much more complex. Its foci were small, hidden, and chronic, and generally caused no local effects. The organism responsible was usually a streptococcus, but this might be of any one of 16 strains differing not in their cultural features or reaction to sugars, but in their selective action on the different systems of the body. This fact had been dramatically shown by the work of Rosenow in 1914–16.

In 1916 Dr. Cotton had admitted into hospital a woman whose case was of definite historical interest. Her father had died of melancholia at 64, and on the death of her mother from paralysis at 80 she had become depressed, agitated, and self-accusatory. Her upper teeth were missing and her lower badly decayed. After two years 11 bad teeth were extracted, and two months afterwards she had permanently recovered. This case aroused his interest in sepsis as a causative factor in mental disease, and had marked the starting-point of his fruitful work in this field. It showed the usual ætiological factors; heredity and the psychogenetic factor of the mother's death, either of which might account for the condition. It had nevertheless been cured by the removal of the most uninteresting feature of the trouble. Her disorder was, in fact, a "septic psychosis." Dr. Hunter also recited another case, this time of acute mania simulating dementia præcox, which had yielded to the extraction of four impacted molars. The problem was whether to wait till the symptoms abated, or to operate while the patient was still violent. Each case must be judged on its merits, but the risk of operating was one which could be safely run. Impacted and

[1] Journal of Mental Science, October, 1923.

nerupted teeth were frequently associated with ıental disorder; in 120 patients of Kopeloff and his olleagues, reported on in 1923, 15 had 49 such teeth. n Dr. Hunter's judgment the dental history and egree of sepsis found in the cases he had quoted were ommon to most of the cases of severe mental disorder ı children and adolescents.

The commonest form of psychosis was the "septic" sychosis; sometimes it existed alone, but it was more ften a complication of other and severer conditions, nd the best hope that any psychotic patient could ave was that his trouble might prove to be largely r entirely due to the influence of a septic focus. In r. Cotton's experience the teeth of all patients, hatever their sex or the nature of their psychosis, ere infected. The stomach was a septic focus in 83 per ent. of men, the tonsils in 76 per cent., and the minal vesicles in 2 per cent. In 10 per cent. there ere serious lesions of the colon. Of women 73 per cent. ad septic tonsils, 76 per cent. a septic stomach, 0 per cent. a septic cervix, and 30 per cent. serious olonic lesions. The observations of Dr. T. C. Graves ad given similar results. His figures for teeth and onsils were lower than those of Dr. Cotton, but his gures for the cervix corroborated the American ones, nd he reported a high incidence (39 per cent.) of ear psis and a 10 per cent. incidence of nasal sinusitis. he relative importance of the various foci, said Dr. Iunter, depended not on the respective incidence in iem of sepsis, but on its virulence, amount, and aronicity. The important factor in oral sepsis was ıe number of sockets, rather than the number of eth, affected. Its degree depended also on other onditions, such as septic gingivitis, tartar deposit, yorrhœa, the number of devitalised and crowned eth, buried roots, unerupted teeth, &c. Gold bridges ere an important source of sepsis, of a kind particuırly liable to produce neurotoxic effects. Teeth arboured much more infection than tonsils ever ould, especially since bony tissue was involved. This ıst factor explained the virulence of nose and ear ıfections. Dr. Hunter welcomed a new era in sychiatry, in which the first measure of treatment ıould be the removal of all septic foci with the help f the surgeon and radiographer; when every mental ospital should be as well equipped and staffed for ental and surgical work as it was now for medical ork. He expected the greatest triumphs of this new pplication of antisepsis, however, in the realm of revention.

Discussion.

Sir BERKELEY MOYNIHAN (Leeds) spoke of the elation of septic foci to gastric and duodenal ulcers. ardiac conditions, he said, could be much improved y the treatment of gall-bladder lesions in particular, nd all had a septic origin except congenital heart isease. If operation on distant organs could benefit ıe heart it could also benefit the mind. He had perated on mental patients for gall-bladder, in the ıce of opposition from physicians and relatives, with onsiderable success for 30 years. The progress of ırgical knowledge of the abdominal viscera was ampered by the lethargy of physiologists, who would o well to bring their researches more closely into line ith clinical requirements. It was a mistake to ithhold surgical aid on account of the severity of the ıental state; as the speaker put it, he never let a atient die of one disease because he happened to ave another as well. He wanted to know why some atients with septic mouths withstood infection hile others fell easy victims. The question must be ound up with the problem of immunity, about which ıe greatest authorities knew practically nothing. Sir erkeley Moynihan hailed the recognition of the edical effects of sepsis as the most illuminating iscovery of the century.

Dr. CHALMERS WATSON (Edinburgh) said that in ıvestigating for sepsis it was essential to study the rine. The condition of the stool was another valuable ource of information. Nearly every case of mental isorder, migraine, and the troubles of everyday life, as associated with some septic discharge from the bowel. This could easily be proved by a double Plombières douche, for whereas the second injection into a healthy bowel came back almost perfectly clean, from a toxic bowel it was returned nearly as turbid as the first. This result, obtainable from 99 out of 100 patients in a general or mental hospital, gave clear proof of a severe disturbance of the balance between the saprophytic growths and the forces which kept them within bounds. Cleansing of the colon was therefore an important therapeutic measure.

Dr. H. A. COTTON (New Jersey, U.S.A.) said that every mental patient was sick physically, though he might have a deceptively healthy appearance. He recalled good results from non-protein irritant therapy, in the use of which, however, Birmingham had surpassed anything he had seen. A method had recently been adopted in America which fulfilled Dr. Watson's suggestion of cleansing the colon. It gave excellent results, but needed a conscientious nurse to operate it; it was a Plombières douche prolonged to an hour and a half or two hours, using about twenty gallons of water, and was given before abdominal operation. Dr. Cotton considered that American work on the colon was more highly developed than anything else in this branch of medicine. He laid stress, however, on the importance of clearing up all the primary foci as well. The "overload" factor was too often forgotten. When a focus was removed, the overload causing the more obvious symptoms was relieved and the patient improved, but that did not mean that he was yet free from severe handicap. Other foci must be looked for, or the trouble might return. In support of Dr. Hunter's concept of the "septic psychosis," he remarked that many people might have sepsis and avoid insanity, just as many people might drink to excess and remain sane; there was, none the less, alcoholic insanity. Though he was enthusiastic about irrigation, he advocated picking and choosing, and believed in any method that produced results.

Dr. T. C. GRAVES (Birmingham) referred to Bruce's "Studies in Clinical Psychiatry," published 21 years ago, in which appeared the fundamental conception that the real disease lay deeper than the chronic toxæmia, and was rather a failure to form antibodies. He described a typical case, cured by non-specific protein therapy and by surgical treatment.

The patient was a single woman, born in 1906 when mother was aged 44, and the youngest of five. The mother, though never certified, had had three nervous breakdowns and suffered from gross oral sepsis. Three other children had chronic nasal disease. At 3 years old patient had scarlatina with left otitis media; the discharge continued till she was 8 and there was recurrence in her teens. She was clever at school, reserved, good at music, and possessed initiative and thought for others. She was never alert, however, and delayed in answering questions. Menstruation occurred once each at 16, 17, 18, and 18¼. At last age the aural discharge became profuse and made her leave work. After mastoid operation next year periods became regular, 4/28. Patient at this time became depressed and developed ideas of persecution. Auditory hallucinations developed, and she was certified in July, 1926. On admission she showed complete disorientation and was noisy, mischievous, and violent. She manifested catatonia and waxy flexibility. These symptoms coincided with the pre-menstrual phase. The skin showed chronic papular staphylococcal eruption. There was discharge from left ear; the tonsils were small and septic; there was pus in right nose, mucopurulent discharge from endocervix. A carious tooth was extracted.

Eight intravenous injections of T.A.B. vaccine were given at five-day intervals during August. No immediate mental improvement followed, but the patient ceased to lose weight. The permeability of the choroid plexus was 3·64, lower than normal. In September she became more composed, though depressed—a reversion to an earlier mental phase. In October an acute exacerbation of the skin eruption followed a general sinus irrigation. The cervix was treated, and in November the tonsils were removed and the sinuses again washed out. By end of December the skin eruption had cleared up, patient had gained a stone, and showed interest in music. The permeability quotient was normal at 3·02. A second course of protein therapy and ultra-violet light was given in January. In February both antra were drained and ear discharge diminished. Definite physical and mental improvement followed, and she was discharged recovered in the summer—better than she had ever been.

This case, said Dr. Graves, showed the law of anticipation in heredity. He suggested that psychotic heredity might be made up of a number of components, in this instance possibly transmitted familial infection. The case also illustrated the serious effect of sinus disease on the reproductive function.

Dr. D. K. HENDERSON (Glasgow) said that Kopeloff and Kirby had divided 120 cases of mental disorder into two groups, one of which was treated surgically while the other was left alone. The percentage recovery-rates for manic depressives and cases of dementia præcox showed no advantage for surgical treatment. Dr. Hunter had judged from one case, which was an example of involutional agitated depression which should never have been sent to the chronic ward. The prognosis was good from the first, and the case had followed a normal course. The term "septic psychosis" was quite unnecessary, and it was dangerous to say that because something existed in a given mental case, then that something was the specific agent. Mental patients had been studied in connexion with the various branches of medicine and surgery for some years, but the recovery-rate had not been materially improved. Mental disorder was a much more complex matter than the discussion had shown. A fair amount of mental illness, indeed, followed the very therapeutic surgical measures which were advocated.

Dr. W. F. MENZIES (Staffordshire) said that the presence of sepsis in mental cases had long been recognised, but in perhaps 300 times as many cases sepsis existed without producing mental disorder. Thus as a causative agent it appeared to be only secondary. It had been shown that the normal and mentally disordered subjects reacted in much the same way to tests of basal metabolism, blood picture, blood-sugar, hepatic and renal efficiency, blood pressure, oxygen absorption, and sensitiveness of the thyroid, pituitary and adrenal glands. Signs of chronic intestinal toxæmia were the same in the sane as in the insane. Vaccines had proved very disappointing and erratic in their results. The problem of the offending organism cried out for team-work on a national scale. The toxic agent might be a product of bacterial katabolism or of the hydrolysis of amino-bodies in food; it exercised its effects as an irritant to the afferent visceral neurons and endocrines, and as a blood infection. There were many ill-known visceral reflex arcs from and to the whole splanchnic area, biologically developed for defence. Any increased splanchnic irritation, as in intestinal toxæmia, would enter the field of consciousness as one of the many vague expressions of "feeling ill"—e.g., headache, giddiness, nausea, and depression. The problem must be studied from the simplest forms of mental disorder, such as acute mania and simple melancholia, which were more nearly allied to primitive emotional phenomena than the complex mental states of paranoia, schizophrenia, epilepsy and obsession. The hopefulness of advanced phthisis and the depression and irritability of bacterial toxæmia were the analogues of mania and melancholia, and many other examples could be cited. They showed that there was normally a stream of reflex currents passing through the basal ganglia and brain-stem which, if amplified, were presented to consciousness as dysphoria provided that they could be freely corticalised. If, however, the connexions with higher centres were interrupted in any way, dysphoria could not arise. Rigidity, as in destructive lesions of the neothalamus or lentiform nucleus, was always associated with euphoria. Pathological euphoria was the expression of the increased blood-flow due to the irritation of a moderate amount of toxins circulating in the cerebral vessels. Perhaps increased permeability of the cerebral reticulo-endothelial system admitted toxins which confused the cortical association paths. Physicians and surgeons missed a great chance of helping psychiatrists when they omitted to describe their patients' emotional subjective tones.

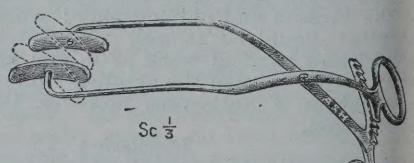
Mr. WATSON-WILLIAMS (Bristol) complained that otologists saw only selected mental cases who had ear trouble. Quite apart from mental hospital practice, however, the otologist saw many of the milder mental disturbances associated with infection in the nose and ear. It was always a problem to decide which neuroses were caused by the infection, and which cases were suitable for surgical treatment. It was almost possible to formulate so distinctive a clinical picture of the mental state which accompanied nasal accessory sinus disease, that this condition could be suspected when physical manifestations were lacking. The patient, when tactfully questioned, would confess lack of power to concentrate, a tendency to worry over trifles, and inability to make a decision. It was because patients could not decide to submit to operation that the surgeon had opportunities of seeing the stages of their mental degeneration. When mentality was restored abruptly by the removal of a septic focus it was impossible not to admit some causal connexion between the physical and mental states. Describing several cases, he remarked that it was the people without much pus who were most liable to mental disturbance.

Dr. W. A. POTTS (Birmingham) suggested an answer to the question why some victims of toxæmia developed mental symptoms and some did not. In those who manifested mental disorder the condition had generally been longer established, and more pathogenic factors were operating. Extraordinary results would be obtained if septic foci were treated early instead of after they had produced dangerous symptoms. The psychogenetic factor also called for prompt treatment, before the patient became inaccessible.

New Inventions.

TONSILLAR FOSSA PRESSURE FORCEPS.

THE instrument shown in the illustration is a modification of the Courtney-Yorke pattern, but differing in a few important details. It has curved instead of straight handles, and ends which are kidney-shaped and movable, to allow of more accurate adjustment to, and hence compression of, the tonsillar fossa. It can be applied to either tonsil and can also be used in the reverse position. The instrument has, however, been specially designed for use in conjunction with the hæmostatic tonsillar clamp, since it does not interfere when left in position on the one tonsillar fossa with the application of the hæmostatic clamp to the other tonsil and the subsequent dissection of the latter.



Messrs. Allen and Hanburys Ltd. are the manufacturers.

L. GRAHAM BROWN, M.D. Oxf., F.R.C.S. Eng.

ST. GEORGE'S HOSPITAL.—In spite of economy at this hospital the excess of expenditure over income last year was £9462, the cost of maintenance being nearly double what it was in 1913. Unless an additional sum of £20,000 a year can be assured the time must come when it will be necessary greatly to curtail the work undertaken.

PROPOSED BURNING OF AN OLD HOSPITAL.—During the outbreak of small-pox which occurred about 25 years ago the Edmonton Urban Council used a wooden building as an isolation hospital. Having no further use for the building, which comprises some 50 tons of material, the public health committee have advised that it should be burnt, rather than dismantled. If the wood were sold it might cause "an outbreak of small-pox or, at any rate, a public panic." The district medical officer's opinion is that there would be no risk of infection.

Reviews and Notices of Books.

OUTLINES OF DENTAL SCIENCE.

Vol. I. *Dental Anæsthesia.* By G. F. RAWDON SMITH, M.D., Lecturer on Dental Anæsthetics, University of Liverpool. Pp. 160.

Vol. II. *Dental Bacteriology.* By R. A. BRODERICK, M.B., L.D.S., Lecturer in Bacteriology to Dental Students, Birmingham University; Dental Surgeon to the Children's Hospital, Birmingham. Pp. 144.

Vol. III. *Dental Materia Medica.* By PROSPER H. MARSDEN, M.Sc., Ph.C., F.C.S., Lecturer in Materia Medica and Pharmacy, University of Liverpool. Pp. 155.

Vol. IV. *Dental Prosthetics.* By J. D. LOGAN, L.D.S., Lecturer on Dental Mechanics, Edinburgh Dental Hospital. Pp. 218.

Vol. V. *Dental Radiography.* By C. A. CLARK, L.D.S., Consulting Radiologist to the Royal Dental Hospital. Pp. 98. Edinburgh: E. and S. Livingstone. 1926. 7*s.* 6*d.* per volume.

THIS series of volumes when completed is intended to cover the whole range of dental science. Seven further volumes are promised, so that the series will eventually cover 12 volumes of about 150 pages each. This country has lagged so far behind others in the production of dental literature that any effort to provide a comprehensive account of dentistry deserves welcome. These volumes contain much that is of interest but are not all of equal merit.

The first volume, on *Dental Anæsthesia* by Dr. Rawdon Smith, is written with a genuine understanding of the needs of the dental student and practitioner by one who has had an extensive experience of dental anæsthetics. It is clearly written and covers the ground ably. The account of the administration of nitrous oxide is particularly good. The section on the administration of gas by the nasal method might have been fuller with advantage, since an increasing number of dentists give gas themselves by this nasal method. The statement that there are no bad after-effects is not always correct. The prolonged use of nasal gas, in the opinion of many anæsthetists, puts a severe strain on the right heart and many patients take a considerable time to recover. It is an extremely useful method but should not be abused by attempting to induce a lengthy anæsthesia which is more safely gained by ether, and a word of warning to this effect might have been included. Among the contra-indications of gas, affections of the thyroid gland should have found a place. We are glad to see that the author favours the use of ethyl chloride as an anæsthetic, especially for children. He states that an anæsthesia of from 60 to 70 seconds can be obtained. In our experience it is quite easy to get an anæsthesia of nearly two minutes in the case of children without running any risk of overdose. Ether, chloroform, and the various mixtures and sequences of anæsthetics are dealt with briefly but adequately. A chapter on local analgesia is included, presumably for the sake of completeness; it is doubtful, however, if this important branch of dental anæsthesia, which is entirely in the hands of dentists rather than anæsthetists, is appropriately treated in a book of this kind. The few pages devoted to local analgesia are of no value to the student and might have been omitted. It is stated that modern dentistry should be made painless, and the suggestion is made that cavity preparation can be carried out without pain by anæsthetising the pulp through a layer of healthy dentine by means of a special syringe. Practising dentists know, however, that this method has long been abandoned as useless, and, indeed, is a cause of pain. The last chapter on the medico-legal aspects of anæsthesia is a useful summary of the legal status of anæsthesia. While this book does not compete with the larger text-books devoted to anæsthetics in dental surgery, it is a useful and practical presentation of the subject which the dental practitioner should find helpful.

The volume on *Dental Bacteriology* by Mr. Broderick follows the usual lines. It contains a certain amount of abbreviated general bacteriology, the space being devoted specially to the flora of the mouth. From the examination point of view it may be useful, but we are sceptical whether the reader will gain from it any clear idea of what infection and immunity really signify. Toxins, immunity, opsonic index, vaccine treatment, and anaphylaxis are discussed in a chapter on bacterial products and results and cover just 16 pages. Even more inadequate are the two pages describing the Wassermann reaction.

Dental Materia Medica, by Mr. Marsden, is a useful compendium of drugs which have been or still are used in dentistry. The author might with advantage have devoted more space to discussion of the pharmacological action of drugs where the student really ought to know it. Many of the preparations described are practically obsolete or of doubtful value. Gelsemium as a remedy for neuralgia is mentioned and an appropriate prescription given. It is stated that untoward symptoms may arise, but no hints are given to enable the dental student to recognise them. In the chapter on hæmostatics the author states that ferric chloride is a "somewhat objectionable hæmostatic, as it is deleterious to the teeth and has a strongly acid reaction. It may be looked upon as a last resort." Modern teaching is that the use of ferric chloride to stop hæmorrhage after tooth extraction is quite unjustifiable. It causes severe sloughing and may lead to secondary hæmorrhage. In Conditt's (not Condett, as stated in the book) method of using silver in root canals the preparation used is not silver nitrate as stated, but an unstable compound of silver and ammonia from which metallic silver is readily precipitated by the use of a reducing agent. The method of its preparation might well have found a place. A useful drug not mentioned is chromic acid, which in 5 per cent. strength is widely used in the treatment of acute ulcerative gingivitis.

The volume on *Dental Prosthetics*, by Mr. Logan, is a practical manual of workshop mechanics. The author evidently has a daily familiarity with all that he describes. His standpoint is an individual one and not every practitioner will agree with all that he has to say. His book is stimulating and useful; it is longer than the other volumes of the series, yet even 200 pages is small compass for so large a subject. Some of the sections are too brief to be of much value, but on the whole Mr. Logan has performed his task with much skill and has written a really practical and useful manual.

The last volume of the series, on *Dental Radiography*, is the shortest and one of the best. Mr. Clark was the pioneer of dental radiography in this country and its evolution to a high state of efficiency owes much to his skill and enthusiasm. He has produced an excellent book which should find a wide welcome. An increasing number of dentists take their own radiograms, and though they can hardly hope to equal the technical excellence of such an expert as Mr. Clark, there is no reason why they should not produce photographs adequate for most purposes. It is highly desirable that every dentist using an X ray apparatus should have a working knowledge of electricity, for it is foolish to use such a powerful agent without knowing its possible dangers. Those who read this book carefully will learn much from it. The account of the installation, care, and uses of a radiographic apparatus is clear, concise, and practical. This is certainly the best book of the series. A special word of praise should, we think, be given to the reproductions of radiograms. They are among the best we have ever seen and reflect much credit on both the radiologist and the publishers.

THE OPERATIONS OF SURGERY.

Seventh edition. By R. P. ROWLANDS, O.B.E., M.S., F.R.C.S., Surgeon to Guy's Hospital, Lecturer on Surgery to the Medical School; and PHILIP TURNER, B.Sc., M.S., F.R.C.S., Surgeon to Guy's Hospital, Lecturer on Surgery to the Medical School. London: J. and A. Churchill. 1927. Vol. I., pp. 1046; Vol. II., pp. 896. £3 10*s.* each volume.

THIS book has long been established as a reliable guide to the operating surgeon, representing the best in current thought and practice. The seventh edition has been thoroughly revised and brought up to date. The operations described are for the most part those performed by the authors, both surgeons of large and illuminating experience, so that their remarks carry weight, and the descriptions of the difficulties which may be encountered and how they may be overcome are particularly helpful and practical. Here and there only are departures from generally accepted teaching, or small omissions. In the account of operations for empyema the reader will not find precise instructions how to deal with an interlobar collection of pus; in the decortication of lung operation the shock observed when the rigidly attached lung is suddenly freed is not emphasised. We cannot agree with the statement on page 792 of Vol. I. that it is difficult to obtain perfect analgesia by local methods for resection of ribs. As a rule, local anæsthesia can be brought about easily and effectively for these cases. In operations for necrosis of the long bones, an account of how to deal with those cavities at the upper end of the tibia, for instance, close to the articular cartilage would have been appreciated. Arthroplasty of the hip is scarcely more than mentioned, but the mature judgment of the authors may well regard it as an operation very rarely indicated. Whitman's operation for ununited fracture of the neck of the femur does not appear, though it is probably the best for this condition. It is interesting to note that the treatment for hallux valgus which the authors regard as giving the best results is not that usually performed.

In Vol. II. there is very little that calls for comment. It is full of good advice resulting from the mature judgment of experience and worthily maintains the tradition handed down by the original authors. The descriptions given of many rather unusual operations, such as that for ectopia vesicæ or the removal of a lingual goitre, will be particularly helpful when the occasions arise. We have not found an account of the useful extra-peritoneal approach to the lower ends of the ureters through a median incision, but this is one of very few omissions.

"Rowlands and Turner" is likely to keep its place as a popular guide for the novitiate surgeon, for whom, with its interesting accounts of actual cases, it is particularly adapted. Very seldom will he consult its pages without finding the very information and guidance that he seeks.

THE METHODS OF CLINICAL DIAGNOSIS.

By ALEXANDER GEORGE GIBSON, M.D., F.R.C.P., Honorary Physician to the Radcliffe Infirmary; and WILLIAM TREGONWELL COLLIER, M.D., M.R.C.P., Honorary Assistant Physician to the Radcliffe Infirmary. Illustrated. London: Edward Arnold and Co. 1927. Pp. 398. 12*s.* 6*d.*

THOUGH assisted more and more every year by scientific methods, diagnosis still remains to a very large extent an art. It is therefore a difficult subject to teach adequately in a book which can at the most indicate the main lines. This new volume does succeed in getting down to fundamentals, and in putting before the reader "the technique of examination, of what to look for and how to look for it." A good survey of the different regions of the body to be examined is followed by a more detailed description of the various systems, wherein sections on the interpretation of symptoms and physical signs are elucidated by a summary of the conditions found in certain diseases of each system. The student is encouraged to make inferences from the moment of his first glance at the patient, amplifying or modifying these as the history of the condition becomes clear and the physical examination proceeds. The section of the book devoted to the cardiovascular system is especially good; a short summary of the "criteria of a healthy heart" is a wise inclusion. It is satisfactory at last to find in print the statement (p. 83) "percussion is not an entirely reliable method for estimating the size of the heart." The section on the nervous system is very full, but seems a little out of proportion to the rest of the book, occupying as it does over 80 pages of the total. This section is also more difficult to follow, even allowing for the complexity of the subject. A small point calls for comment in connexion with the examination of the abdomen. On p. 63 the student is advised to press "deeply under the ribs" when feeling for the spleen. A soft, diffusely enlarged spleen may not be felt if too much pressure is used. It is generally better to let the spleen come down and touch the examiner's hand during inspiration than to press deeply. The book concludes with a well-chosen section on clinical pathology and an appendix containing useful tables.

THE HEART AND ITS DISEASES.

By CHARLES W. CHAPMAN, M.D., M.R.C.P. Edinburgh: E. and S. Livingstone. 1927. Pp. 216. 8*s.* 6*d.*

THE aim of this book is to provide for the busy practitioner a brief summary of the current teaching in cardiology. Its general arrangement follows the accustomed scheme. The opening chapters deal with the anatomy of the heart and its conducting tissues, and with symptoms and physical signs. Rheumatic, syphilitic and other types of heart disease are briefly reviewed, and special chapters are devoted to the consideration of marriage and anæsthesia in cardiac patients. Many similar small books on the heart have been published in recent years, and the present volume does not present any features likely to render it more popular than its predecessors. The illustrations, most of which are taken either from Cowan and Ritchie's or from Price's works, are good, but the text leaves much to be desired. For example: "In auricular disease characterised by marked dilatation and a state of over-excitability, incomplete attempts to contract the auricle (auricular fibrillation) occur." Such statements fail entirely to give a true picture of the condition described, and can only lead to confusion in the mind of the reader. One great fault in this as in many other small books is that the author attempts to deal with detail instead of being content with setting out general principles.

THE INVERT.

By ANOMALY. London: Baillière, Tindall and Cox. 1927. Pp. 160. 5*s.*

THIS little book brings forward for consideration, with a frankness that deserves a return, certain phases in the question of homosexuality because their explanation will be of real use to those who find themselves at a loss to provide practical advice for patients and penitents of confused sex—cases in which the coöperation of the doctor and the priest is often needed. An introduction by Dr. Thouless, Ph.D., lecturer in psychology at the University of Glasgow, should be read, as it clears the author's way excellently, and justifies the writing of the book on practical grounds. There is no reason to desire the continuance of an ignorance of the problems of inversion which precludes their receiving either instructed or charitable deliberation. A mean is possible between popular conversation—and no one wishes to see the subject debated in drawing-rooms—and the gutter publicity which such topics receive to-day; such a mean the author has succeeded in maintaining, and his counsel is given with real literary accomplishment.

MANUAL OF BACTERIOLOGY.

Eighth edition. By ROBERT MUIR, M.A., M.D., Sc.D., LL.D., F.R.S., Professor of Pathology, University of Glasgow; and the late JAMES RITCHIE, M.A., M.D., F.R.C.P. Edin., late Professor of Bacteriology, University of Edinburgh. Revised with the coöperation of CARL H. BROWNING, M.D., D.P.H., Professor of Bacteriology, University of Glasgow; and THOMAS J. MACKIE, M.D., D.P.H., Irvine Professor of Bacteriology, University of Edinburgh. London: Humphrey Milford, Oxford University Press. 1927. Pp. 821. 16*s*.

IT comes as something of a shock to realise that "Muir and Ritchie" with the appearance of the eighth edition celebrates its thirtieth birthday. With sadness we note that for the first time the hand of James Ritchie, who so long and so worthily shared the responsibility for its production, has played no active part in the preparation of the current volume. Prof. Muir has done well in his endeavour to fill the gap, by enlisting the coöperation of Prof. Browning and Prof. Mackie, so that as the book now stands it is wholly the product of the Glasgow school. There is one at least small but notable improvement on former editions. Throughout the period covered by our recollection the opening phrase of the first chapter of Muir and Ritchie has been "At the bottom of the scale of living things . . .," and we remember the dismal impression conveyed by this phrase and by the rest of the introductory chapter, of the awful dullness of bacteriology. Only active contact with the subject served to dispel that impression. The book has, indeed, been revolutionised by the disappearance of this initiation; the introductory chapter has been rewritten and has gained much thereby. Throughout the book, indeed, the revision has been adequate, while the size has not obviously increased. Some of the half-tone blocks show signs of wear, and the coloured illustrations are disadvantageously collected together at the beginning of the volume. Its price is worthy of note by the student, as comparing favourably with that of many American text-books.

"Muir and Ritchie" is what it has always been, sound, well-balanced, up to date, and a safe and accurate source of reference.

MONGOLISM.

Beitrage zur Kenntnis der Mongoloiden Missbildung. By Dr. W. M. VAN DER SCHEER. Berlin: S. Karger. 1927. Pp. 162. M.12.

Dr. van der Scheer's comprehensive monograph is based on a study of 348 cases of mongolian idiocy seen by him during his four years' tenure of an inspectorship of asylums in Holland. He deals first with the various theories that have been advanced to explain the occurrence of this abnormality. G. Shuttleworth's view is that the mongolian idiot is an exhaustion product and occurs as a result of conditions adversely affecting the maternal reproductive organs —e.g., advanced age, frequent childbearing, toxic influences, nervous depression, and alcoholism. Syphilis or tuberculosis may be contributory factors, but are not specific causes of mongolism. F. G. Crookshank, on the other hand, in a recent work takes the view that mongolism is an atavistic return to a more primitive type. As a result of a study of his series of cases, Dr. van der Scheer comes to the conclusion that the above views are incompatible with the facts observed by him. Comparing the histories of 79 mongols with 76 non-mongolian idiots, he finds that no greater importance can be attached to the state of the mother's general health when a mongol is produced than when the child exhibits any other form of weakmindedness. The main facts which emerge from his investigation are as follows: Very many mongols are the last born; many mothers of mongols are of advanced age at the time of birth of the mongol; in families with mongols, abortions and stillbirths are frequent; blood relationship of parents is of no importance; hereditary factors are of little importance; the father's age is of no importance. In 56 per cent. of Dr. van der Scheer's cases the mongol was the last born, and in 45 per cent. the mother's age was greater than 40 years; he confesses himself forced to the view that there exists a factor inhibiting normal childbirth, that this factor is as specific as the condition; he regards it as more likely to exist in the uterus than in the ovary. A very full account of the post-mortem appearances of a number of cases of mongolism is included. In the brain there is often found a hypoplasia of the infundibular region and hypophysis, the floor of the third ventricle and the interpeduncular region. In many cases mal-developments or absence of the ossa nasalis have also been observed. Dr. van der Scheer suggests that in these cases there is probably a developmental defect in the median plane of the skull, and he advances the theory that at a certain stage in embryonic development a too small amniotic sac prevents the normal extension of the fœtus. The head is thus compressed against the chest, and for a time the fœtus remains too strongly flexed. This theory would bring mongolism into line with other abnormalities of mechanical origin. The various findings which Dr. van der Scheer considers support this view are discussed in great detail in the text, which is well illustrated. An extensive bibliography of the literature of mongolism completes the monograph.

THE CARE OF THE FACE.

By OSCAR L. LEVIN, M.D., Chief of the Dermatological Clinic, Cornell University. London: William Heinemann, Ltd. 1927. Pp. 225. 6*s*.

IF the author's sources of information are reliable, no less than £29,000,000 are annually dissipated in America on "skin foods," "face-moulders," "unwrinklers," and a heterogeneous variety of cosmetic procedures. While we cannot compete with such stupendous figures in this country, evidence of the general prevalence of the cosmetic habit is not lacking, and it will be recalled that in a recent legal process it was stated that the institute concerned earned an average income of £600 per week. Dr. Levin's attempt to educate and rescue the willing victims of cosmetic chicanery is commendable. He has a wide knowledge of pathology and a racy style, usually absent in medical treatises, and if the ordinary layman can be prevailed upon to read it, particularly the lay woman, real good should follow. For the author has managed to compress an enormous amount of valuable information and what the average individual understands by "horse sense" into his book. There is an excellent chapter on quackery, in which the dangers of X rays for hypertrichosis, the evils of hair-dyes and depilatories, plastic surgery, paraffin injections, and a number of other cosmetic procedures and preparations are ably discussed and criticised. Hypertrichosis is again dealt with in another chapter, and again the treatment by X rays is condemned, and it is to such blemishes of presentation that the difficulty of reading the book is due. This duplication of material is a characteristic feature throughout and there is very little attempt at orderly arrangement, so that the impression is gathered that a number of lectures have been very roughly recast and thrown together without regard to sequence or classification. Even a medical man may find it difficult to thread his way through the tortuous channels of fact, theory, and invective, doubtless justified, with which the author has coloured his pages, and laymen will be more sorely tried. The type in the text is all of one size, little use is made of subheadings, and there is no index, its place being taken by a short glossary. The line drawings that illustrate points in the text might as well have been omitted; in a word, the format has not done much to lighten the author's very difficult task.

MOTHER INDIA.

By KATHARINE MAYO. London: Jonathan Cape. 1927. Pp. 391. 10*s.* 6*d.*

IN the first chapter the authoress, an American woman, states her object in writing this book.

"Leaving untouched the realms of religion, of politics, and of the arts," she writes, "I would confine my inquiry to such workaday ground as public health and its contributory factors. I would try to determine, for example, what situation would confront a public health official charged with the duty of stopping an epidemic of cholera or plague; what elements would work for or against a campaign against hookworm; or what forces would help or hinder a Government effort to lower infant mortality, to better living conditions, or to raise educational levels, supposing such work to be required."

The storm of controversy that has been raised by this book, and the diversity of the comments that have been passed upon it by critics of wide experience, bear testimony to the striking quality of the evidence which is presented and of the conclusions which are reached. There is here told a story of a struggle against forces of inertia and superstition which, by incurious residents in India, are only dimly apprehended. It is a story which it is impossible even to epitomise in this review. Suffice it that the account of the child-marriages, the obstetric practices, and the sanitary habits imposed by Hindu religion make it difficult to understand how more than a minority of women survive childbirth. And the treatment of animals which it sanctions is such as to harrow the medical no less than the lay reader. Miss Mayo imports into her style qualities of descriptive vividness, of irony, and of literary restraint which are well offset by the invariable documentary support which she gives to her statements. Her sojourn in India being short compared with that of many Englishwomen, she writes her book in the light of the recorded experiences of others no less than in that of her own experiences. Her statements are abundantly substantiated by references to written sources—to Government reports, to speeches made by Indians in Council or Legislative Assembly debates, to Mr. Gandhi's writings, to Indian medical journals and reports, and to numerous books written by Englishmen with long experience of India. Far from representing a superficial impression formed during a hasty tour, the book is based on a vast deal of reading, and covers a period which ends with the last months of 1926.

It is difficult to exaggerate the interest of this book. Medical interests are interwoven with ethnological, psychological, and historical material in a whole which is presented in language so well chosen as to make the book a masterpiece of descriptive writing. And it should bring especial pleasure to English readers. What has been said by Miss Mayo, an American woman viewing our administration from the outside, could never possibly have been said by an English author without incurring the charge of self-interested partiality. For throughout the book, implied on almost every page though never in so many words expressed, is to be found a tribute to our rule in India for which, in sincerity and tacit eloquence, it would be difficult anywhere to find an equal.

VENEREAL DISEASE.

Its Prevention, Symptoms, and Treatment. Third edition. By H. WANSEY BAYLY, *M.C.*, M.R.C.S., L.R.C.P., Hon. Secretary, Society for Prevention of Venereal Diseases; Medical Officer in Charge, V.D. Department, St. George's Hospital. London: Faber and Gwyer. 1927. Pp. 242. 10*s.* 6*d.*

Mr. Bayly's book in its third edition is divided into five sections; the first section, as might be expected from the author, is on the prevention of venereal disease. It is a robust statement of the possibilities and the efficacy of immediate self-disinfection in men. The second section on syphilis is good, and includes some useful pictures of sores and rashes. In this part of the book the requisite pathological tests are fully described. Mr. Bayly gives a "combined routine treatment course" for syphilis, occupying 106 days, modified for different individuals, which seems adequate. The treatment prescribed is both sound and modern. Gonorrhœa is fully dealt with in the third section, which contains no particularly new features. Some minor horrors frequently associated with venereal disease are discussed in the fourth section, and the fifth is devoted to description of arrangement of consulting-room and to case-taking, as well as to the more important questions of sterility, impotence, neurasthenia, and the problem of how soon after infection a man should be allowed to marry. On the last matter we wish to join issue with the author; in our opinion, even with expert modern treatment, a year from the date of infection with syphilis is too soon to allow a man to marry; the proviso that the man continue treatment after marriage may well be thought unnecessary by the patient, and the possibility of infecting a wife or child is one not lightly to be dismissed. Three coloured plates and 74 illustrations adorn the text, and the book as a whole can be recommended.

BACTERIAL VACCINES.

Their Position in Therapeutics. By LEONARD S. DUDGEON, C.M.G., C.B.E., F.R.C.P. Lond., Professor of Pathology, University of London, and Director of Pathology, St. Thomas's Hospital. London: Constable and Company. 1927. Pp. 87. 7*s.* 6*d.*

THIS is a short monograph based upon the wide personal experience of its author. Prof. Dudgeon expresses himself tersely and dogmatically; the fact that he writes of his own experience and views and presents these without much reference to the work of others makes for easy reading. The subject is set out in a sane and balanced manner and without any suggestion of misleading enthusiasms. Prof. Dudgeon acts the part of judge rather than advocate, and for this all interested in vaccine therapy should be grateful. There is not much in the book which calls for critical comment. We note that the author kills his vaccines by formalin; that he has found no superiority in sensitised vaccines; that he standardises his vaccines by an opacity method; that he has no doubts as to the superiority of the autogenous variety; and that he pronounces definitely against this form of therapeusis in acute infections. All of this is sound doctrine, and it is pleasant to find it clearly and authoritatively stated. Non-specific protein therapy, in common with all varieties of vaccine treatment which are irrational, such as haphazard streptococcal vaccine administration in pernicious anæmia, goitre, "intestinal toxæmia," and so forth, is roundly denounced. As a guide to what bacterial vaccines and allied substances are, when they are useful and when they are to be avoided, this little book is the best we have encountered.

TOPOGRAPHY OF THE SKELETON OF THE LARYNX.

Die Topographie des Kehlkopfgerüstes. By Dr. W. MINNIGERODE, Assistant Surgeon in the Second University Clinic for Throat, Nose, and Ear Diseases in Berlin. Munich: J. F. Bergmann. 1927. Pp. 25 + 17 plates of illustrations. M.18.

IN this anatomical study, for which he has utilised drawings left by the late Gustav Killian, Dr. Minnigerode has produced a useful and readable account of the relations of the framework of the larynx, the hyoid bone and laryngeal cartilages to the soft structures of the larynx, and especially to these parts seen in the laryngeal mirror. He has made use of dissections, frozen sections, and, in a few instances, of radiograms, and has provided an interesting text to accompany the 68 excellent drawings. The most practically useful are those on Plate XVI., which gives five drawings of the larynx as seen in the mirror, with the several cartilages distinguished by shading. A careful and thorough piece of work.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 17, 1927.

THE TREATMENT OF EPILEPSY.

ADVANCES in the treatment of epilepsy have recently been made in three directions. Empirical modifications in the metabolism of epileptics have been found to possess therapeutic value. The introduction of luminal and its sodium salt has provided a new pharmacological weapon, a discovery which has been contemporary with considerable additions to our knowledge of the mode of action of sedative drugs upon the nervous system. Lastly, an increasing recognition of the importance of a psychological approach to the problem of epilepsy, although perhaps this has been exaggerated in some quarters, has had a beneficial effect upon treatment. Recent attempts to treat epileptics by altering their metabolism date from 1921 when GEYELIN introduced fasting as a therapeutic measure. It was found that complete starvation for 10 or 12 days produced a marked improvement in the condition of epileptic patients. Acting on the assumption that the beneficial element in the starvation was the associated ketonæmia, WILDER, PETERMAN, and others attempted to obtain the same result by administering a diet sufficiently rich in fats and poor in carbohydrates to produce a marked ketosis. Such a ketogenic diet was found to be as efficacious as complete starvation, and has now been used widely enough for certain conclusions to be drawn as to its value. All available data are derived from the treatment of children only. The diet must be accurately planned to produce ketosis and at the same time to supply the needs of a growing child.[1 2] It has been found that unless the ratio of ketogenic to antiketogenic foods—that is, of fats to carbohydrates and proteins—exceeds 1·5 to 1·0 by weight, ketosis does not develop. The ratio required to effect improvement may be as high as 5 to 1, and a 3 to 1 ratio has in many cases been maintained for months. This involves both a great restriction of sugar and an unpalatably large consumption of fat, and thus the same difficulties are encountered as in the dietetic treatment of diabetes in children; an outbreak of fits in a child that was previously responding well to the treatment can usually be traced to clandestine sweet-eating. Different observers report a very similar proportion of cases benefited. TALBOT, METCALF, and MORIARTY state that 30 per cent. of the children treated became free from attacks, whilst HELMHOLZ reports a cessation of fits in 31 per cent., and states that 23 per cent. were improved to a less extent and 46 per cent. were unaffected. Since the children freed from attacks have been under observation for not more than two or three years, it is impossible to say whether the improvement is permanent, and a ketogenic diet cannot at present be regarded as in any sense a cure for epilepsy. It seems, however, to be worth a trial in selected cases where the coöperation of intelligent parents can be obtained, and especially when the child has failed to respond to treatment with the bromides and luminal.

The fact that a ketogenic diet benefits even a proportion of epileptics raises questions of great theoretical interest. It has not been proved that the therapeutic value of starvation and a diet rich in fats is due to the associated ketosis, and another explanation is suggested by recent investigations, which appear to have established the existence of a definite metabolic abnormality in epileptics. POPÉA and VICOL in 1925 noted in a small number of epileptic patients that the level of the blood cholesterol was abnormally low, and regarded this as a result of the convulsions. Dr. S. H. G. ROBINSON, Dr. RUSSELL BRAIN, and Dr. H. D. KAY, in a recent issue of THE LANCET,[3] published the results of their investigation of the blood cholesterol in over 100 epileptics and a similar number of controls. These workers confirmed the association of a low blood cholesterol with epilepsy and were able to show that the fall in the blood cholesterol was not the result of the fits, since it began some hours before a convulsion, which took place at or about the time when the level of cholesterol in the blood was lowest. KILLIAN and OSNATO have also observed a low blood cholesterol in epileptics, so that this phenomenon has now been noted by three independent groups of workers. Its significance, however, has still to be discovered, and is likely to remain obscure until there has been a considerable advance in our knowledge both of the physiology of cholesterol and of the metabolism of nervous tissue. ROBINSON, BRAIN, and KAY point out that cholesterol is an important constituent of nerve-cells and that the association of a low blood cholesterol with epilepsy receives support from clinical experience; for the level of this blood constituent is low at the menstrual period when convulsions are specially prone to occur in epileptic women, and an abnormally high blood cholesterol is found during starvation and in patients receiving a diet rich in fats. Here, perhaps, is an indication of the direction in which we should look for a possible rational basis for the therapeutic value of starvation and a ketogenic diet.

Dr. TYLOR FOX'S article on the use of luminal-sodium in the treatment of epilepsy, which we publish in this issue, should prove of practical value to all who have to treat epileptics, and also raises points of great interest to investigators. His results clearly demonstrate that epileptics acquire tolerance to the drug and that its withdrawal is followed by an increase in the number of fits, so that the patient may be actually worse than before treatment. These facts emphasise the need for caution in the use of luminal, and support the practice of keeping it in reserve until the bromides have been tried and found wanting. Dr. FOX found that in the majority of cases the mental state of his patients was greatly improved as a result of the reduction in the number of their fits which luminal effected. In a few cases, however, the patients became more asocial and violent than before, and administration of the drug had to be stopped. How are these diverse results to be explained? Some light is thrown upon this problem by recent advances in the pharmacology of sedative drugs. We are not here discussing in detail the possible causes of epilepsy, but it may be said that the most useful hypothesis as to the nature of the physiological disturbance in a convulsion is that it is a sudden and explosive discharge of neural energy. PAVLOV has shown that the pharmacological effect of the bromides is to strengthen the inhibitory processes of the cerebral cortex, and

[1] Talbot, F. B., Metcalf, K. M., and Moriarty, M. E.: Boston Med. and Surg. Jour., 1927, cxcvi., 89.

[3] Robinson, S. H. G., Brain, W. R., and Kay, H. D.: THE LANCET, August 13th, p. 325.

PICK has demonstrated that luminal acts in the same way. Both these drugs, therefore, produce by physico-chemical means a state of the cortical neurons which is the very reverse of activity or discharge, and this is presumably the source of their therapeutic value in epilepsy. The treated epileptic is saved from the usurious drain of his fits upon the energy of his nervous system, and can spend his neural income on higher activities whose nature depends upon his natural disposition. Dr. FOX points out that those patients whose character deteriorated as their fits diminished had a previous history of asocial behaviour. PAVLOV'S researches illuminate also the part which psychological factors may play in the precipitation of epileptic attacks; he was able to produce the symptoms of neurasthenia in dogs by overstraining their capacity for inhibition of conditioned reflexes. Such experiments suggest that in a potential epileptic a neurosis which taxes the patient's inhibitory powers may facilitate the epileptic discharge. Hence, psychological understanding plays a necessary part in the treatment of epilepsy. The patient must be saved from any avoidable mental stresses which may be associated with his domestic environment, and he must, if possible, be provided with a quiet occupation which calls for canalised and orderly neural processes. This in itself involves no small degree of training in inhibition, and in selected cases active psychotherapy has undoubted value. We have discussed pharmacological, metabolic, and psychological modes of treating epileptics; he will be the most successful therapist who realises that these methods are not mutually exclusive. Neither research nor treatment is likely to be useful if it does not envisage man as approachable on different levels of reality, and as being at the same time a collection of molecules, an integration of physiological processes, and a mind.

SLAUGHTERING AND SLAUGHTER-HOUSES.

Captain C. W. HUME'S interesting address to the Section of Agriculture of the British Association at Leeds will focus attention once more on the conditions of slaughter prevailing in this country. As he points out, the three criteria by which the present system of slaughtering must be judged are humanitarian, hygienic, and commercial. While any modification of slaughter-house construction or procedure may affect all three aspects of the question, it is particularly in relation to hygiene that medical opinion has a right to be heard. In this respect we must reluctantly admit that Captain HUME'S indictment of slaughtering conditions in this country is justified. With rare exceptions our principal towns have failed to provide public abattoirs which meet the requirements of modern hygiene, either as regards construction or facilities for meat inspection. It is the case, as Captain HUME says, that a large proportion of all the animals slaughtered is still dealt with in about 20,000 private slaughter-houses, most of which are primitive in construction, and afford no proper facilities for detection of disease either in living animals or their carcasses. The methods of handling the carcasses also leave much to be desired. Outbreaks of food poisoning, not infrequently traced to meat which has been free from the manifestations of disease on inspection, may quite well be due to contamination with intestinal contents, for carcasses are constantly exposed to this risk during the process of dressing. It may be, as Captain HUME suggests, that the blame rests principally with the National Federation of Meat Traders' Associations, but local authorities are not entirely guiltless. Even in areas where power has been obtained, ostensibly on public health grounds, to provide public abattoirs and prohibit private slaughtering, control has been placed in the hands of committees whose main object has too often come to be the reconciliation of traders' interests with public profit, rather than the protection of the community from disease. In most of our large public slaughter-houses the staff appointed for the purpose of veterinary and meat inspection is incomparably inferior in numbers to that of continental abattoirs, and the accommodation for those who are engaged in this work is not conducive to its proper accomplishment.

Captain HUME'S main thesis, however, is concerned with the practice of slaughtering. Here, it should be clearly understood, the prime consideration is humanitarian. The hygienist is drawn into the controversy only indirectly to support or refute subsidiary arguments brought forward by the protagonists of one or other point of view. It is possible that the keeping quality of meat is slightly affected by any additional excitement which animals may experience at the sight of blood, over and above the inevitable agitation attendant upon their being driven within enclosed spaces by strange hands. This effect must be accentuated if a method of killing is used which is uncertain, and may involve repeated violence before the animal becomes unconscious. It is likely, however, that the keeping quality of meat is also lessened by methods such as the pole-axe or the humane-killer, which delay bleeding and thus cause retention of a certain amount of blood and lymph in the muscular tissue. It appears, therefore, that there is need, from the hygienic standpoint, of a method which will entail the least excitement of the animals prior to slaughter, and will yet permit of prompt and complete bleeding. None of the supporters of the humane-killer has satisfactorily answered the arguments, based on scientific observation and experiment, which Dr. LEONARD HILL put forward in our columns in 1923 [1] in support of the Jewish system of slaughtering. This method requires, however, great skill and the maintenance of instruments in a perfect condition. As now practised, it also involves the violent preliminary of "casting" large animals, though a much less brutal method of getting them into position, devised by Mr. WEINBERG, of Manchester, is now on trial.

It is an undoubted fact that animals suffer needlessly at the hands of apprentice slaughterers, whether they practise with the knife, the pole-axe, or the humane-killer, more especially with the two first-mentioned implements; but in skilled hands none of them need cause suffering to anyone but the sympathetic onlooker. The mere act of killing, irrespective of method, is so repulsive to many of us that we should follow the road to vegetarianism travelled by THOREAU if we set out, as he did, to provide ourselves with food by our own unaided efforts, and it is significant that not a few of the advocates of the humane-killer are vegetarians. If the division of labour which is a part of civilisation enables the rest of us to evade this issue, it does not relieve us of the responsibility of ensuring that our food is procured without cruelty. The use of the humane-killer may not be the ideal method of slaughter, but the agitation on its behalf will have been worth while even if it only leads to greater humanity in the application of the older methods.

PERIODICAL MEDICAL EXAMINATIONS.

WE have received from the People's League of Health a detailed account of the deputation to the Minister of Health on June 28th last, with a list of those figuring on the deputation, proving its representative character. The deputation submitted a group of resolutions through Lord BURNHAM, under which the Government was asked to consider the effect of unemployment and unemployment insurance benefit on the health and habits of the nation, both from the psychological and physiological aspects; and the necessity for new regulations to prevent waste and shortage of perishable foods during the summer by the establishment of adequate cold storage. But the main object of the deputation was to impress upon the Minister of Health the need for instituting periodical medical and dental examinations for all persons benefiting under the National Insurance Acts. The proposal of the League was that every insured person, when accepted as a panel patient, should be medically examined by his doctor and the result recorded; such an examination applying also to dentistry when this additional benefit is available under the Acts in question. The representatives of the League anticipated the obvious criticism of this proposition by pointing out that it was an economical one, having regard to the results that would be obtained in productive efficiency. The deputation was introduced by Lord BURNHAM, who confined his remarks to the consideration of periodical medical and dental examinations, and asked, in the name of the League, that a departmental or inter-departmental committee should be appointed to consider the question. The speakers who followed included Colonel F. E. FREMANTLE, Prof. P. LELEAN, Sir ROBERT ARMSTRONG-JONES, Mr. LAMING EVANS, Prof. WINIFRED CULLIS, Dr. WILLIAM HUNTER, Mr. E. B. TURNER, Dr. C. S. MYERS, Mr. R. C. JEWESBURY, Mr. LEWIN PAYNE, Mr. R. LINDSAY, Dr. OTTO MAY, Dr. R. J. LLEWELLYN, Mr. C. J. BOND, and Dr. W. A. POTTS, and all, out of practical experience in varied departments of medicine, surgery, psychology, dentistry, and health administration, brought arguments to show that the absence of early treatment of pathological conditions was the common factor in maintaining the incidence of disease in the country.

In our correspondence columns this week will be found a letter from a group of doctors, which goes over ground that is in some ways the same. The signatories to the letter—the Advisory Committee of the Regular Medical Examination Association—plead with the insurance companies or any other organisation to improve the relations between individual citizens and the medical profession by facilitating a scheme for the regular medical examination of families. The Association is in touch with a scheme emanating from a body entitled the Family Medical Services Ltd., which is instituting an insurance policy to cover the financial risks incurred by families in respect of medical service, this being described as the one item of family expenditure which owing to its uncertainty cannot be satisfactorily provided for in any way save by an insurance scheme. The policy proposes to meet the financial embarrassment of heavy doctors' bills, and not to pay for occasional medical attendances in the case of minor complaints. The scales of premiums and benefits can be obtained from 20, York-street, Manchester, these being graded in accordance with whether it is intended to insure against the charges of general practitioners only or against the cost of operations, in which case there are, of course, additional charges. The promoters of the combined schemes, it will be seen, while not insisting like the People's League of Health in regarding periodical medical examinations as the surest way of promoting individual health, are advocating for private patients much the same preventive means as the League desires for panel patients. It may be that medical examination can be dispensed with in taking out a doctors' bills policy—such seems to be the intention; but if the scheme should meet with supporters, the result will be the calling for medical attention in many circumstances where this is not done. Only experience can say if this indirect method of detecting early disease can be put upon sound financial grounds, the added professional work being adequately remunerated.

Mr. CHAMBERLAIN, in reply to the People's League of Health, was unable to do more than express a benevolent wish that the ideals of the League might be successful. He was unable to consider the advisability of making periodical health examinations compulsory or of grafting such examinations, with any voluntary basis, on to the National Insurance Acts. Nor was he prepared to set up a committee to consider the whole matter, holding that the machinery would be too expensive, while incidentally he touched upon other difficulties which would confront those framing any legal measures to carry out the proposals of the League. The massed figures, as used by various speakers on the deputation and by the Minister of Health, followed the familiar pattern—that is to say, it was shown that if so many men lost so many hours a day through invalidism, the aggregate loss to the country was colossal; and it was also shown that the examinations of so many patients on so many occasions over such and such periods would take up a colossal amount of time. On both sides the arithmetic has remained unchallenged, and displayed the difficulty of the issues. The view of the Minister clearly was that the cost to the country of periodical examinations was, at the present time, too great to be contemplated, while he may be inferred to have held that the economical gain following upon higher standards of general health could not be made a certainty unless compulsory examinations were instituted. This measure he thought would be impossible for adults, though feasible and successful in the early years of life.

UNIVERSITY OF LEEDS.—Sir Edward Allen Brotherton, of Leeds, has given £100,000 to the University for the provision of a Brotherton library.

LONDON MEDICAL EXHIBITION.—At the Central Hall, Westminster, daily, from Monday, Oct. 3rd, till Friday, Oct. 7th, between the hours of noon and 6.30 P.M., the London Medical Exhibition will be open to members of the medical profession. This annual display of the latest adaptations of research to medical and surgical treatment is always attended by a large proportion of medical practitioners both from at home and abroad, and this year there are indications that the exhibition will be the largest which has been held since 1905, the year of inception. Every effort is to be made to minister to the convenience of those who visit the exhibition, and a spacious tea room and a reception room have been provided. Those who have not yet received their cards of admission can obtain them on application to the Secretary, London Medical Exhibition, 194–200, Bishopsgate, London, E.C., or at the Central Hall during the exhibition week.

Annotations.

"Ne quid nimis."

THE LANGUAGE OF SCIENCE.

THE recent meeting of the British Association at Leeds has once again been the occasion for various complaints in the lay press about the obscurity of the language used by scientific men when they expound the results of their thoughts, observations, and experiments. It is perhaps natural that those who have to make the path straight for the public should lay stress on the efficacy of words, but, plainly enough, human thought is always a little in advance of human language, and any thought which is progressive must constantly be devising new words and reorganising and rearranging those already available. It would perhaps be better if old words were left alone; a good many difficulties arise from attempts to delimit and define words in common use for some special technical purpose. Such has, however, been the usual practice, and brand-new words, such as "gas" are exceedingly rare; scientific terminology has evolved and not been specially created. However, whatever its origin, it is, of course, unintelligible to an untrained audience. Such must needs be, for it is a shorthand so indispensable that within each scientific topic the intimates have generally developed a kind of super-shorthand, which is not always easy to distinguish from slang. It is hardly possible to contemplate doing without "anaphylaxis"; the professor of English literature in the University of Cambridge has a particular abhorence of "antibody"; what would he say of "immune serum" if he knew about it? In the great majority of instances there is no difficulty in making scientific work intelligible to a lay audience which is willing to be attentive for a sufficient number of hours. The troubles are that the time occupied would certainly be desperately long if every technical word had to be treated by periphrasis, and that a great many of the topics arising at a meeting such as that of the British Association would be of no interest whatever to an average gathering of citizens. The public is beginning to believe that natural knowledge is of real importance and is anxious to know what is going on. Their desires are being met to a considerable degree and much admirable work is being done in making the results of scientific research available to the mildest curiosity; some first-rate examples have issued in recent years from the lectures at the Royal Institution, and it is difficult to avoid reading recipes for health which at any rate purport to be in line with the very latest discoveries in medicine. So much indeed is being done in this way that we do not believe there is any reason why the technical austerity of the language of the British Association should be in any degree tempered. That historic assembly is a meeting of scientific men who want to talk and sometimes to listen to one another; it does for them by way of a personal gathering what *Nature* does for them by way of a periodical.

SPA TREATMENT OF RHEUMATIC HEART DISEASE IN CHILDREN.

OF late years various attempts have been made abroad to treat cardiac rheumatism in children by hydrological methods after the acute signs have subsided. E. Feer,[1] of Zurich, recommends a mild Nauheim cure in after-treatment, and considers that even when compensation is beginning to fail it may be useful to give CO_2 baths at home, or at Nauheim or some similar spa, in conjunction with prolonged rest. Piatot,[2] again, has reported encouraging results from the use of effervescent baths, subthermal rainbaths, and subaqueous douches in recent cases of rheumatic endocarditis in young subjects, and considers that "cases should be submitted to treatment of this kind three to six months after the onset of the rheumatism, even if the joints are still painful." It is interesting, therefore, to find that physical treatment of the condition is being used as a routine at the Auguste-Viktoria Kinderheilanstalt at Bad Oeynhausen in Westphalia. This home has 220 beds for children of 4 to 14 years of age who are recommended for admission by the medical officers of neighbouring municipalities, which pay the whole or part of the cost of treatment. Though the patients are chiefly rheumatic, there are also anæmic and pre-tuberculous children. A special house of 25 beds has been set aside for cardiac cases, of which the majority are, of course, rheumatic. After a preliminary period of observation lasting three days, during which these children are kept in bed and the pulse, temperature, and blood pressure are recorded, as well as their exercise-tolerance in response to a standard test, the patients are treated by baths, under very careful supervision. The first two or three baths are of 2 per cent. saline or 3 per cent. for the older and stronger children, and are given at a temperature of 93° F.; the first lasts from 6 to 10 minutes and the subsequent ones last for from 12 to 15. Usually three baths a week are given. Unless symptoms such as dyspnœa develop the children are later allowed to go on to CO_2 effervescent baths, which are given at 90° F., and also last for 12 to 15 minutes. The baths are taken at 7 A.M. after a light breakfast, and the children rest in bed for two hours afterwards; in addition, they have two hours rest daily in the open air under a shelter. No salicylates or other drugs are given, except to the anæmic children, who receive iron and arsenic, together with a natural effervescent water containing arsenic and sodium chloride from the Max Spring at Dürkheim. All the children do graduated exercises for not more than ten minutes at a time under the strict supervision of an experienced instructress, and rest for a quarter of an hour afterwards; deep breathing exercises are not permitted to the cardiac cases. The complete course of treatment lasts six weeks. The children are examined on arrival and before discharge and once a week during their stay at the home. The case records are subsequently sent to the municipal medical officer who recommended admission, and he, in turn, examines the child as a routine three months after discharge, or sooner if the authorities at the home consider it advisable, and sends a copy of his report to the medical officer of the home. If necessary the child can then be sent back for a further four weeks' treatment, or the treatment may be repeated in successive years. Those in charge of the treatment consider that their results are very good.

PRESERVATIVES AND POISONS IN FOOD.

ONE result of recent enactments about preservatives in foods has been the appearance of papers showing that a number of natural or simply prepared food substances supply their own preservatives. Fruits such as cranberries and bilberries contain benzoic acid; boiled sugar sweets, caramel, and smoked fish contain formaldehyde; and Mr. Scott-Dodd has shown that cacao beans may contain from 0·02 to 0·08 per cent. of boric acid, which apparently is also found in some untreated wines. Though it is improbable that sulphites will be found in natural products it might constitute a good fighting defence, in proceedings under the Food and Drugs Acts, to show that products containing sulphurous acid had been grown on the slopes of an active volcano. Poisons or substances more definitely poisonous than preservatives are also found in foods. Not long ago[1] we reported the discovery of arsenic in shell-fish, especially crustaceans, and it may be noted that Mr. R. E. Remington in the United States has found this substance in both

[1] See THE LANCET, 1926, ii., 1229.

smoking and chewing tobaccos in amounts reaching over gr. ¼ per lb., though the prohibitive cost of tobacco in this country makes this form of arsenical poisoning impossible for any but the wealthy. It is at first rather startling that foods and other articles which are more or less consumed by man should contain these ingredients naturally, and that these discoveries should be made at a time when we are seeking by enactment to obtain foods which are free from them. Consideration shows, however, that this is quite in the normal course of events. Plants are only to a limited extent selective in their abstraction of nourishment from the soil, and are likely to take up such small proportions of substances like borates as they can tolerate or to allow arsenates partly to take the place of phosphates. The inhabitants of the sea live in a medium which is a dilute solution of all the crust of the globe. It is essential for them to tolerate traces of all the elements and they may be able to utilise rather unusual ones in certain circumstances. These facts, so far as preservatives are concerned, are being found out in the course of exploring the natural defensive properties of food—properties which need exact investigation rather than intelligent surmise. In general the amounts of toxic or objectionable substances are small. Their presence under natural conditions must make the analyst carefully consider in every case whether there is good evidence of their having been artificially added; it gives no reason for supposing that it does not matter how much of these banned substances are contained in any food. The main object of restrictive legislation is to remove the possibility that any normal diet may contain them in harmful quantities.

OVARIAN HORMONES.

THE problem of the internal secretions of the ovary is becoming extremely complicated. There now seem to be four, and possibly five, different types of ovarian secretion—a sex-producing hormone, an œstrus-producing hormone, possibly two hormones derived from the corpus luteum, and a substance causing parturition. Hitherto, the interstitial cells have been generally regarded as the source of the hormone which influences the development of female secondary sexual characteristics, but opinion is by no means unanimous about this, and it is pointed out that these cells are not present in all species. Certain experimental facts, nevertheless, are well established. If both ovaries are removed in a young subject, not only do the uterus and external generative organs fail to develop, but the secondary sexual changes also either do not occur or are greatly modified; in older individuals regressive changes take place. If a suitable piece of ovary is transplanted into a spayed female, the sexual characteristics return, and if ovarian tissue is grafted to a male the animal becomes feminised. Moderate experimental exposure of the ovaries to X rays has been found to cause atrophy of the follicles (incidentally preventing formation of corpora lutea) whilst leaving the interstitial cells either unaltered or hypertrophied. Under these circumstances the uterus and secondary sexual characteristics also remain fully developed, which affords the chief evidence that the sex-producing hormone is derived from the interstitial cells and not from the follicles.

The œstrus-producing hormone (œstrin) and those formed by the corpus luteum seem to be intimately associated with the events of the œstral and menstrual cycles, and A. S. Parkes has shown that hormones from the corpus luteum are apparently necessary for the continuance of pregnancy. It has also been suggested by Parkes and C. W. Bellerby [1] that during pregnancy the corpus luteum exerts an œstrus-inhibiting influence which can be over-ridden by injections of œstrin, a substance which in sufficient dosage will terminate pregnancy both in its early and its later stages. This effect of œstrin in early pregnancy has been confirmed by L. Brouha and H. Simonnet, and the view that an œstrus-inhibiting factor is present at this time is strengthened by the observation that œstrin can readily be extracted from ovaries of pregnant animals and is also present in the placenta. Brouha and Simonnet [2] have also lately studied the effects of injections of œstrin in a series of animals before puberty, in adults in full sexual activity, and after the menopause, and in castrates, and their investigation has fully confirmed the original researches of E. Allen and E. A. Doisy. They found that injections made in animals just before puberty brought on œstrus just as it did in the other experimental animals; this induction of œstrus was always accompanied by growth of the uterus and by other characteristic changes in the genital tract. The use of œstrin in clinical work seems to be indicated when effects leading to menstruation are required, but so far its use in human beings has not been satisfactory. Œstrus and menstruation are not homologous, and in menstruation it is necessary to take into consideration other factors, notably the part played by the corpus luteum in inducing pre-menstrual changes in the endometrium. According to R. Schroeder,[3] ovulation occurs in the human subject between the fourteenth to the sixteenth day after menstruation, and the corpus luteum which is formed prepares the uterus for the succeeding œstrus. On the twenty-eighth day and during menstruation the corpus luteum is degenerate (W. Shaw [4]). Experiments have been reported by E. C. Dodds, F. Dickens and S. Wright,[5] and by E. Allen [6] in which definite menstrual phenomena have been induced in a monkey and in oöphorectomised monkeys and women by injection of follicular fluid. The work of Parkes,[7] however, indicates that the cycle cannot be entirely dependent either on Graafian follicles or corpora lutea, for his experiments with X ray sterilisation show that periods continue after both follicles and corpora lutea have been destroyed.

Lastly, there is the extract, for which Prof. W. E. Dixon is responsible, which can be obtained from the ovary at certain periods, especially during pregnancy, and on injection into animals brings about a secretion from the posterior lobe of the pituitary body into the cerebro-spinal fluid. Prof. Dixon believes that this plays a considerable part in the emptying of the uterus at the termination of pregnancy. The researches of Allen and Doisy with œstrin have certainly given a fresh stimulus to research on ovarian internal secretion, and it should not be long now before the fruits of this work are seen in clinical medicine.

[1] Jour. of Phys., 1926–27, lxi., 562.

THE AMERICAN HEALTH UNIT.

MODERN society has inevitably created a demand for larger administrative units in the conduct of public health, with resources adequate to their functions. Development in America is discussed in a booklet called "The County Health Unit," issued by the Milbank Memorial Fund. It describes a conference called recently by the Governor of New York State (Hon. A. E. Smith) to draw attention to the advantage of organising rural public health work on a county basis. Mr. Smith's views were thus expressed in his message to the State legislature in January, 1926: "The unit for local public health work should be the county, with a full-time qualified county health officer who should be made responsible for the conduct of local health matters within his jurisdiction, with any such supervision as the State may be required to give in an advisory capacity. Such an organisation has been possible under the law (in New York State) for several years; yet only one county—namely, Cattaraugus—has seen fit to take advantage of it, and with the very best results in promoting the physical welfare of the inhabitants. Other States have made notable progress in county health administration, and there are now some 307 such organisations throughout the

country." By a law of 1924 the State reimburses half the expenditure of the county boards of health, and the advantages which have apparently accrued to Cattaraugus county so impressed the conference that it commends the "larger health unit" plan to the other rural counties of New York State.

The immensity of the task before the United States was indicated by the statement that in the 48 States there are over 3000 counties, some 2700 of which are predominantly rural. At the opening of the century the mortality-rate of the rural districts was about 75 per cent. of that in the cities; of late years it has been 8 per cent. or 10 per cent. higher. As a rule the county is a suitable unit but in sparsely inhabited areas several counties would have to combine. It is not proposed to abolish the town and village health officers; they are to become deputies of the county officers. On the other hand, State aid will not be given to villages and towns on the grounds that they are too small to carry on a satisfactory public health programme. A minimum estimate of the staff required for a county unit includes a health officer, two or three public health nurses, a sanitary inspector, and a clerk-stenographer, their total salaries amounting to about $24,000 a year. The health staff of Cattaraugus county now numbers about 40, and to the $56,000 contributed towards their maintenance by the county and the State the Milbank Memorial Fund has added another $65,000. A large proportion of the Fund's income is used to finance rural health demonstrations as models for other districts.

THE SIGNIFICANCE OF A PIRQUET REACTION IN CHILDHOOD.

EVERY medical society worth its salt has its great days—days, or rather evenings, when a paper is read by the author of some "epoch-making discovery." A lively discussion follows, the potential maker of an epoch being supported by his coöperators and the inevitable optimist, and criticised by those whose appetite for the epoch-making discovery has become a trifle jaded. Apparently it was at such a meeting that Dr. Heimbeck read the paper on tuberculosis in nurses, to which reference has already been made in THE LANCET (August 6th, p. 290). It will be recalled that Dr. Heimbeck's Pirquet examination of probationers showed that over 50 per cent. gave a negative reaction, but that after a year or more practically every nurse was Pirquet-positive. What was passing strange was the observation that, of the 43 nurses who developed tuberculosis during their hospital service, as many as 40 had been among the Pirquet-negatives; only three had given a positive reaction when starting work in hospital. Conclusion: the young nurse who is Pirquet-negative in a hospital where she has to work hard and may be exposed to tuberculous infection is in grave danger. The spirited discussion following Dr. Heimbeck's paper included a most interesting contribution from Prof. Frölich on the value, or rather the disadvantage, of a positive reaction, at any rate as far as children are concerned. During the period 1912–15 he carried out a series of Pirquet tests in school-children. In 1925, with the help of Dr. Jörgensen, he re-examined 1830 of the 2400 (approximate figures) 7-year old children who, in 1912, had given a positive reaction. Of these persons, now 20 years old, as many as 223, or 12·2 per cent., had contracted some form or other of tuberculosis. On the other hand, of the 332 Pirquet-negative 7-year old children examined in 1912, only 9·3 per cent. were found in 1925 to have developed some clinical form of tuberculosis. If a conclusion is warrantable on the basis of these figures alone, it is that a positive Pirquet reaction as early as the seventh year of life is no cause for rejoicing—rather the reverse. As for the intensity of a Pirquet reaction, it was found that the subsequent incidence of tuberculosis was considerably greater among the children who had given a violent reaction than among those whose positive reaction had been mild. There has been a tendency during the last few years to regard the Pirquet test as so thoroughly "worked out" as to belong rather to routine and the clinician than to research and the research-worker. But the Norwegian workers have shown that this test may still have some surprises in store for us, and that it may be exploited in clearing up some of the still unsolved problems of immunity in connexion with tuberculosis.

THE REGISTERS OF APPLEDORE.[1]

PAROCHIAL documents, such as transcripts, registers, and churchwarden's accounts, are always interesting to read as preserving items of manners and customs which have either passed away or else are survivals of older customs. "But the Iniquity of Oblivion blindly scattereth her Poppy," and in many cases such documentary evidence has perished owing to lapse of time, to the carelessness of those who should have been the guardians of the records, or to the lust for destruction of so-called reformers. It is therefore a praiseworthy task that Dr. Cock has undertaken in stringing together pearls of information for the benefit of readers who have neither the time nor the ability to seek out and decipher the sometimes crabbed writing of registers and transcripts. Registers of births, deaths and marriages were first ordered to be kept in every parish by Thomas Cromwell, Henry VIII.'s bully, in 1538, so that shady personage has at least one good deed to his credit. Transcripts, copies of the registers, were sent up twice a year to the Archidiaconal and Consistorial Courts, and the series for Canterbury is, says Dr. Cock, the most perfect in England. From these transcripts the little book before us has been compiled. The documents examined are for Appledore and Eboney, and date from 1563–4 down to 1812, with a regrettable gap for the period 1642–1660—i.e., the Civil War and the Commonwealth. Dr. Cock notes that in the year 1591 there were several entries of burials of poverty-stricken people, such as, "John Cox a householder but extreme poore," and says that, according to the Rev. J. Johnson, vicar in 1700, most of the inhabitants were very poor; he surmises that this poverty was due in great part to malaria, which, as Appledore and Eboney are just on the edge of "The Mesh"—i.e., Romney Marsh—is very likely true. The Mesh in the eighteenth century and on into the nineteenth was a curious and somewhat uncivilised place in many ways. Most people who have any knowledge of the district will recall the incident recorded in the life of the Rev. R. H. Barham, of "Ingoldsby Legends" fame, who was curate of Snargate and Warehorn in 1817. In a house in the former village he was one day invited to partake of dinner, the dinner being what was known as "jump short pie." Barham ate his portion, praised it, and asked why it had such an odd name. His host explained that it was lamb. "You see, sir, the young lambs on the Mesh try to get over the drains; a many of 'em jump short, tumble in, and get drowned. Then we hook 'em out and put 'em in a pie. Have another help, sir?"

Of medicine Dr. Cock makes frequent mention. In referring to the preventive use of quinine he says that when this drug was first sold in the neighbourhood, about 1850, it cost £8 an ounce. Small-pox is noted in the register as a frequent cause of death, and in 1773, between Sept. 13th and Oct. 16th, four deaths are entered from this cause. In 1725 two men and their wives did public penance in church, and in 1728 a young woman did the same; all for breaches of the Seventh Commandment. In 1753 Peter Hook, the parish clerk, dropped down dead while repeating the Confession. Dr. Cock reminds his readers how the parish clerk used to lead the responses, and how often the whole service was a duet between parson and clerk. It is not generally known that one of the duties of the clerk is to read

[1] Notes from the Transcripts and Registers of Appledore, Kent. By F. William Cock, M.D., F.S.A. 1927. Pp. 17. 1s.

the Epistle when the priest is single-handed at the service. There is an appendix specially dealing with medical men in Appledore, and in reference to one of them, William Durand, buried October, 1792, Dr. Cock quotes an advertisement from the *Kentish Gazette* dated July 14th, 1770, wherein Mr. Durand informs the neighbourhood of his intention to practise, and sets forth his qualifications for the same in no unassuming terms. Of one Daniel Price, who combined the professions of preacher and doctor, Dr. Cock notes that he used to bleed himself profusely for any ailment, and in the end bled himself to death. Readers of *Waterton's Journals* will remember how he used to bleed himself to a pint or so and also take 20 gr. of calomel, for Demerara fever, without, however, any untoward results. We note that Dr. Cock's delightful little pamphlet is to be sold for the benefit of the Village Hall Fund, and surely the fund should benefit largely. Such information as it contains is not only of interest but of value, and it is only fitting that a medical man, a member of a profession which together with the clergy sees more into the ways and hearts of their fellows than do other men, should have devoted his time to recording these happenings.

THE PATHOLOGICAL EXAMINATION OF FRESH MATERIAL.

IN the course of the elaboration and improvement of laboratory technique there is a tendency for old and simple methods to fall into disuse. For the most part the newer methods have certain obvious advantages, sometimes, however, there is a loss. The paraffin method of cutting microscopical sections affords an example. This method on its introduction offered such obvious advantages over those previously in use that it was universally adopted, and to-day, to the vast majority of those not actually engaged in laboratory work, a section means a paraffin section. The method has the obvious disadvantage that, in the course of embedding, the tissue is submitted to very drastic usage and to the action of solvents which bring about great alterations in the character and contents of the cell. It is only necessary to read some of the descriptions of the older histologists, based upon the examination of fresh tissue, to realise what has been lost by this advancement in technique. Some of the advantages of the examination of fresh tissue were made clear and a simple technique described by Dr. B. J. Terry [1] at the meeting of the Pathological Society of Great Britain and Ireland in July last. This method consists in the examination of moderately thick sections of tissue, the upper surface of which is lightly stained. The sections are rapidly mounted on an ordinary microscope slide and illuminated by a strong beam of transmitted light. Probably this method was new to the majority of those who saw the demonstration, but it was by similar methods that the foundations of histology were laid. The routine examination of the blood forms another example of a procedure in which observation is now made almost entirely upon grossly altered material. In investigating a blood picture the present-day pathologist hardly ever by any chance makes an observation upon the blood as it leaves the vessels, without drying, staining, or mixing with some diluting fluid. Yet, as was well known to earlier workers, the appearances provided by the blood from the time it has left the vessel until clotting is complete may provide interesting and perhaps valuable information. In an address before the Société Médicale des Hôpitaux de Paris, Prof. Hayem [2] pleads for a return to the examination of "sang pur." Prof. Hayem many years ago perfected and described the examination of blood *á rigole*, but it is a procedure which has dropped from the armamentarium of the modern hæmatologist. The principal information to be derived from this method depends upon the rate of formation of the fibrinous network. A characteristic heavy network is quickly formed in pneumonia and rheumatic fever; it is scanty and tenuous in the enteric fevers. Observations upon the presence or absence of a leucocytosis can be readily made at the same time that the fibrinous network is being examined, and the two observations together may frequently give valuable information.

THE SOURCE OF VITAMIN D.

THE resolution of discord gives as much satisfaction in the realm of medical science as in the realm of music. If contradictory views on, for example, the ætiology of an obscure disease are voiced in different centuries, their fusion into a workable theory is a matter for rejoicing; but when the controversy has been waged between two contemporary schools of physiology in our own times, and the views appeared to be irreconcilable if not mutually contradictory, the discovery that both sides are right is wonderful. The ætiology of rickets has been in dispute for a long time. For years one school of physiologists maintained that it was a deficiency disease, due to lack of a vitamin, whereas the evidence supplied by another, the Glasgow school, pointed to lack of fresh air and sunlight as the chief factor in its production. Heated discussions were reported in scientific publications, where each side described ingenious controlled experiments designed to test the theory. Gradually, as our knowledge of the properties of the various accessory food factors, and the symptoms exhibited by those whose diet was deficient in them, increased on the one hand, and the manifold effects of prophylactic and curative radiotherapy developed on the other, the protagonists became less virulent, and it dawned on them and on others that possibly sunlight could in some way compensate for lack of adequate diet. The mechanism whereby this might occur was for a long time obscure. Controlled work among children in Vienna just after the war, combined with results obtained elsewhere, left no doubt that rickets can be prevented or cured by dietetic measures, or by heliotherapy. At the same time K. Huldschinsky made the discovery that rickets could be cured by treatment with ultra-violet light from an artificial source. It thus became clear that the conflicting views of the ætiology of rickets were both correct. The strange fact that light can act as a substitute for diet in this connexion still remained an anomaly, which only slowly resolved itself. The various steps in its resolution, demonstrating the mechanism whereby each of the two factors exercises an antirachitic effect, have been chronicled in our columns during the last few years. The discovery by a number of workers independently that antirachitic potency can be imparted to inactive articles of diet, chiefly fats, by exposure to ultra-violet light first gave an indication of the explanation. This discovery was pushed further, and cholesterol, having the characteristics then known of the "chemically pure" substance, was found to be the constituent of these inactive bodies which were capable of activation. When purified still further, however, cholesterol lost this property. Eventually in THE LANCET of Feb. 5th, 1927, Mr. O. Rosenheim, F.R.S., and Mr. T. A. Webster explained their reasons for concluding that ergosterol, a highly unsaturated sterol, is the direct precursor of vitamin D. In a communication to our present issue (p. 622) the same observers add some further chapters to the complicated story. Their recent work seems to bring the matter to the point at which one can say, with scientific precision and not merely as a guess, that sunlight and cod-liver oil both cure rickets, because sunlight produces in the skin, from which it is absorbed, the substance which cod-liver oil provides ready made. But the position even now is far from being a simple one. Indeed, facts are coming to light which show that the reaction by which the vitamin is formed when ergosterol is exposed

to ultra-violet light is highly complex, and the possibility that the pro-vitamin is not ergosterol at all but an impurity is still not wholly excluded.

SIR WILLIAM GLYN-JONES.

WE regret to learn of the death of Sir William Glyn-Jones, the well-known pioneer in modern pharmaceutical developments, which occurred from cerebral hæmorrhage on Friday last, Sept. 9th, at Vancouver, where he had recently gone to take up the position of chairman of council of the newly formed Proprietary Articles Trade Association of Canada. He did more than anyone of his generation to raise the standard of the pharmaceutical profession.

William Glyn-Jones was born in Worcester in 1869, and spent his whole life in the interests of his chosen calling. As an assistant in a chemist's establishment in the east end of London, he found time to eat his dinners, and was called to the Bar in 1904. But he had already come into public view, for as much as 30 years ago he founded an association to put down certain abuses in the trade of patent medicines which were oppressing the best sort of retail chemists. At that time the sale of some obviously quack nostrums was used by unscrupulous traders to attract customers to their shops, the articles being sold at prices which yielded no profit. Dispensing chemists who did not relish these advertising methods were suffering in their conduct of legitimate business, and the new association was designed to put a stop to the evil by bringing manufacturers, wholesale druggists, and retail chemists together to remedy the situation. Regulations accordingly were made by which no proprietary medicine, the makers of which belonged to the association, could be sold below a fixed minimum price; any retailer who violated the rules was placed on a "stop list" and prevented from obtaining further supplies of any of the "protected" articles. The economics of this arrangement were subjected to certain criticism from medical men; by bringing together the members of all sections of the drug trade, it was demonstrated that what pharmacy had long been looking for—namely, an organised plan of development—had been found. Those who saw in the movement nothing but a plan for securing to chemists a profit on proprietary medicine learned to appreciate that the outcome has undoubtedly been for the public benefit.

Sir William Glyn-Jones used the dominant position in pharmacy which he had now obtained in a worthy way. The formation of the Chemists' Defence Association, the severance from the Pharmaceutical Society's activities of the trading interests of pharmacy, the union of the Society with the British Pharmaceutical Society, and last but by no means least the establishment of the pharmacological laboratories, were all movements in which he played a prominent part. As Member of Parliament for Stepney from 1910 to 1918 he took an active part in the framing of shop hours legislation; he served his craft in Parliament manfully, sometimes in opposition to the medical view, when the National Health Insurance Acts were in the making; and, as an expert on poison and pharmacy law, he influenced legislation in the Dangerous Drugs Acts. In 1918 he became secretary and registrar of the Pharmaceutical Society, which post he held until he took up his important duties in Canada. He was knighted in 1919 in recognition of his eminent services to the pharmaceutical profession.

THE NEW PRINCIPAL OF THE ROYAL VETERINARY COLLEGE.

Prof. Frederick T. Hobday, veterinary surgeon to the King, has been appointed Principal of the Royal Veterinary College of London in succession to Sir John McFadyean. From the time of his qualifying in 1892, he has devoted himself to the various aspects, scientific and practical, of veterinary medicine and surgery. He first attracted the attention of the College authorities by the development of the out-patients' clinic which, as professor of materia medica and therapeutics, came under his control. This valuable work he enlarged from the teaching aspect until two clinical assistants had to be appointed to assist in the administration and teaching. His next activity, which was largely recorded in various scientific and veterinary journals, comprised the investigation of anæsthetics for use in veterinary surgery, and in 1899 the College awarded him the John Henry Steel memorial medal as a recognition of the practical nature of his labours. In 1904 he became editor of the *Veterinary Journal* and shortly after a member of the Examining Board of the Veterinary College, and is now a member of the Council. During the war he was in command of one of the largest of our veterinary hospitals, while scientific medicine owes him a particular debt in that he was one of the chief promoters of the movement which brought into being the Section of Comparative Medicine at the Royal Society of Medicine.

WE regret to record the sudden death, on Sept. 12th, of Dr. Sydney Rawson Wilson, senior anæsthetist to the Royal Infirmary, Manchester. Dr. Wilson, who was 45 years old, has recently been working on impurities in ether, and published in THE LANCET of May 28th last an article on "Ether" Convulsions, which has given rise to much correspondence in our columns. It is feared that he was overcome while experimenting with an anæsthetic.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. R. Thompson is placed on the Retd. List with the rank of Surg. Capt.

J. H. Nicolson and R. Murray to be Surg. Lts.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Comdr. A. G. L. Reade to *Ramillies* for 14 days' training.

ROYAL ARMY MEDICAL CORPS.

Maj. J. A. Clark retires on retd. pay and is granted the rank of Lt.-Col.

Capts. to be Majs. (Prov.): J. W. Malcolm, G. K. Maurice (remains secd.), and R. F. Walker.

Capt. R. Willan, late W. Afr. Med. Serv., to be temp. Lt. and temporarily relinquishes the rank of Capt.

ARMY DENTAL CORPS.

Temp. Lts., Dental Surgs., Gen. List, to be Lts.: J. B. Cowie and R. E. Edwards.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Qrmr. and Lt. W. H. Brown resigns his commn. and retains his rank.

Capt. J. B. Scott to be Maj.

Capt. R. G. Michelmore resigns his commn. and retains his rank.

Lt. J. L. Johnston to be Capt.

General Hospitals: Capt. D. Mallam resigns his commn. and retains his rank.

ROYAL AIR FORCE.

Flight Lt. F. P. Schofield is granted a permanent commission in this rank.

Maj. A. K. Macdonald, Army Dental Corps, is granted a temporary commission as Squadron Leader on attachment to the R.A.F.

Flight Lt. G. A. Ballantyne, D.F.C. (Capt., Army Dental Corps), relinquishes his temporary commission on return to Army duty.

Squadron Leaders: P. H. Young to Headquarters Coastal Area; D. McLaren, to Hospital Orderlies Training Depôt, Halton.

Flight Lts.: G. J. Griffiths to Basrah Combined Hospital; J. M. Maxwell (Quartermaster, Med.) to R.A.F. General Hospital, Iraq.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLI.—THE TREATMENT OF MYXŒDEMA.

THE treatment of myxœdema resolves itself largely into the administration in some form of thyroid extract or thyroxin, the active principle of the thyroid gland. Myxœdema is a true deficiency disease, and thyroid treatment is specific. Stress has also been laid on the necessity of removing any possible cause of thyroid depression which may exist at the time of observation, but in practice it is often found that when the disease has developed to the stage at which it can be diagnosed the causal factors are no longer playing an active part in its production. There may be an antecedent history of hyperthyroidism, the result of emotional stress or some septic process which has caused an exhaustion of the gland, or part of the gland may have been removed. Myxœdema may develop as the end-result of repeated pregnancies, or may appear with the termination of ovarian activity at the climacteric. Generally, however, there is little which can be done from the ætiological aspect of treatment, though it is always advisable to bear in mind the important part played by focal sepsis, intestinal toxæmia, and errors of diet, and to correct these as far as possible. Chief reliance must be placed on the administration of thyroid extract. It is to Prof. George Murray that we are indebted for the observation, in 1891, that the symptoms of myxœdema in human beings could be made to disappear by the subcutaneous administration of sheep's thyroid gland. Victor Horsley, previously to Murray's work, practised transplantation of sheep's gland into the tissues of a myxœdematous patient, but the results of this operation were unsatisfactory then, as they have been since, chiefly owing to the rapidity with which the graft is absorbed. The effects are only temporary and not lasting. Somewhat later it was shown by H. MacKenzie that extracts of thyroid gland taken by the mouth would also control the symptoms of the disease, and this has remained the standard method of treatment to the present day. With the advent of synthetic thyroxin (Harington, 1926), it seems probable that the use of gland extracts will gradually be discontinued, for the synthetic substance should be more dependable than the various preparations of thyroid extract now in use.

The chief difficulties in the past in obtaining satisfactory results in the treatment of myxœdema have been (1) the absence of any reliable method of gauging the dose required. Estimations of the basal metabolic rate are proving of considerable value. (2) The large number of different preparations of thyroid extract on the market and their tendency to vary in strength from time to time.

The Basal Metabolic Rate.

The basal metabolic rate is the rate of energy exchange in the body under basal conditions (after elimination of food, muscular exercise, and so forth). It can be found by measuring the amount of heat given out by the body in a given time, or indirectly by estimating the oxygen consumed per unit of surface area. This is the method employed clinically. A sample of expired air is collected by a specially designed apparatus while the patient is at rest and has fasted for 12 hours over night. The metabolism under these conditions is fairly constant for different individuals, and only varies within limits of plus or minus 10 per cent. In hyperthyroidism it may be as much as 75 or 100 per cent. above normal, whilst in myxœdema it may fall to 40 per cent. below normal. This test affords a means of accurately controlling the dosage of thyroid extract in myxœdema. It is scarcely necessary to point out that it must only be used as a supplement to clinical observation.

Thyroid Extract and Thyroxin.

The preparations of thyroid extract usually employed in the treatment of myxœdematous patients are fresh thyroid gland, desiccated thyroid gland (thyroideum siccum), liquor thyroidei (thyroid solution, B.P.1898).

In practice it is not perhaps sufficiently well recognised that these preparations are of different potency; unsatisfactory results often follow from the indiscriminate use of different preparations in any given case. The strength depends mainly on the iodine content of the substance employed. Of the preparations mentioned, desiccated thyroid is five times the strength of the fresh gland, 1 gr. of thyroideum siccum corresponding to 5 gr. of fresh or whole gland; 5 gr. of fresh gland has the same potency as 10 ♏ of liquor thyroidei. The following comparative table may be of use :—

Thyroid (desicc.) ..	¼ ..	½ ..	1 ..	2 ..	3 ..	4 ..	5 gr.
,, (fresh) ..	1¼ ..	2½ ..	5 ..	10 ..	15 ..	20 ..	25 gr.
,, (liquor) ..	2½ ..	5 ..	10 ..	20 ..	30 ..	40 ..	50 ♏

Since reliable preparations of desiccated thyroid are readily obtainable from most firms, it would seem advantageous to use this extract as far as possible in all cases.

Reference has already been made to the introduction of synthetic thyroxin by C. R. Harington. Clinical reports of its effects in myxœdema are still scanty.

D. M. Lyon and F. A. Redhead[1] report results obtained in two myxœdematous subjects. The metabolic activity of both patients increased immediately and rapidly, one by 26 per cent. and the other by 48 per cent. Corresponding rises in temperature and pulse-rate and decrease in weight accompanied the rise in basal metabolism. W. A. Plummer and W. M. Boothby have also made numerous clinical observations in cases of myxœdema with thyroxin, using the active principle isolated by C. C. Kendall from the gland in 1915. The results are apparently clear cut and almost quantitative when this substance is given intravenously. The myxœdematous symptoms are relieved, and it is calculated that 1 mg. of thyroxin causes an average increase of 2·8 per cent. in the basal metabolic rate, a 10 mg. dose raising the metabolism from minus 40 per cent. to minus 12 per cent. In a large series of cases this figure was remarkably constant. Intravenous administration is not essential; the same effect was obtained when thyroxin was given by the mouth. Thyroxin is now supplied commercially in doses of 0·2 mg., 0·4 mg., 0·8 mg., and 2 mg. to be taken by the mouth. Based on the percentage iodine content of the two preparations, 0·2 mg. of thyroxin (Harington) corresponds approximately in potency to two-thirds of a grain of the desiccated gland.

Management of a Case.

The therapeutic indications are, therefore, clear. The basal metabolism of a patient with myxœdema must be brought to the normal level and there maintained by an appropriate daily dose of thyroid extract or thyroxin in some form. In practice it is not possible to have estimations of the basal metabolic rate made often, and in the ordinary straightforward case it is certainly not necessary to submit the patient to the inconvenience of several estimations. An initial examination, however, may be of considerable value, and will give a good idea of the amount of thyroid extract which is likely to be required to raise the patient's metabolism to normal. To a large extent the basal metabolism runs parallel with the pulse-rate, so that for ordinary purposes the latter will usually be a sufficient guide, especially if it is used in conjunction with other clinical data, notably variations in the patient's weight. It is important to make routine observations when giving thyroid preparations by the mouth, and, owing to the variability in the extracts and in their absorption from the gastro-intestinal tract, to standardise clinically, or by means of the basal metabolic rate, not only the preparation but also the individual patient. After the initial tests it is usually sufficient to note the clinical effects when thyroid is given by the mouth. Most cases of myxœdema are extremely sensitive to this extract, so that it is best to commence with a small daily dose and gradually to increase it at intervals of a week or so until an appropriate maintenance dose has been found. A satisfactory result can usually be obtained by starting with gr. ¼ of the desiccated gland once a day, increasing to gr. ¼

[1] Edinburgh Medical Journal, April, 1927.

twice a day at the end of a week, to gr. ½ twice a day at the end of another week, and later to gr. 1 twice a day. This is an adequate maintenance dose for the average case of myxœdema, and a larger one is seldom required. It is necessary, however, to judge entirely by results, and no rules can be laid down. The patients themselves often rapidly acquire a knowledge of what is the optimum dose for them and can give considerable help to the physician. They should be warned at the start that treatment will have to be continuous throughout their lives, and that successful results depend to a large extent on the systematic supply of thyroid extract in the correct dosage. Since the effects of the remedy are so obviously beneficial, there is seldom any difficulty in obtaining complete coöperation from the patient.

A warning is also necessary as to the symptoms of overdosage. It is often a good plan to stop the routine administration for a day or two each week, or for a few days each month, to avoid any accumulative effects. For the same reason attention to the bowels is advisable. If overdosage does occur, all thyroid should be stopped for a week or two and started again at half the previous dose. The extract should be discontinued during the course of any acute illness, or if any septic process is present, such as tonsillitis or pyorrhœa; under these conditions symptoms of hyperthyroidism are liable to appear if thyroid treatment is persisted with. The symptoms of an overdose are headache, nervousness, palpitations on exertion, diarrhœa, insomnia and mental irritability, and general malaise. There is also excessive loss of weight, tremor, and tachycardia. It is not difficult to detect signs of overdosage at an early stage, for when the myxœdematous symptoms have once cleared up the weight should remain more or less constant at approximately the average normal level of the patient before his illness.

Diet.—The value of any food as far as the thyroid is concerned is to a large extent dependent on its iodine content, and it has been shown experimentally that with an exclusive meat diet, in which the iodine content is low, the gland tends to atrophy. The same result is brought about by inanition. It is advisable, therefore, to see that the diet is adequate in quantity and quality. A mixed diet containing an abundance of fish, fruit, and vegetable is appropriate. Where myxœdema is associated with obesity a very much better result can often be obtained by a moderately severe restriction of carbohydrates. Less thyroid extract is generally required in these circumstances, and this is advantageous inasmuch as these patients often show a tendency to cardiovascular instability.

Cardiovascular Considerations.—Patients with myxœdema frequently have symptoms and physical signs of cardiovascular insufficiency. This may be coincidental or the result of the thyroid condition. The heart usually shares in the process of myxœdematous infiltration, or may be fatty. Arteriosclerosis is not an uncommon complication. In such patients, when thyroid extract is given in quantities sufficient to cure the myxœdematous symptoms, increased work is thrown upon the heart, and it may take time to adjust itself. It is usually advisable, therefore, for this type of patient to remain in bed during the first part of the treatment and to take no unusual exertion. In severe cases a course of digitalis or other cardiac therapy may be given before treatment with thyroid extract is started.

Conclusion.

The most essential features in the treatment of myxœdema are the removal of all sources of thyroid depression and the regular supply to the patient of some form of thyroid extract or thyroxin in the correct dosage. The results are generally satisfactory. The original patient treated by Murray was 46 years old and lived in good health for over 28 years after developing the disease.

THE PHOTOCHEMICAL PRODUCTION OF VITAMIN D FROM ERGOSTEROL.

BY O. ROSENHEIM, F.R.S.,
AND
T. A. WEBSTER.

(*From the National Institute for Medical Research, London.*)

THE recognition of the fact that ergosterol is converted by the action of ultra-violet light into a powerfully antirachitic substance raises new problems of scientific interest, bearing directly on the practical application of the discovery to the prevention and cure of rickets and osteomalacia, as well as to the general control of the calcium balance.

It may be readily conceded that the newly established facts signify a considerable step forward in so far as they place at least one of the elusive vitamins in a group of organic non-nitrogenous substances, immediately related to the sterols, which possess well defined chemical and physical properties.* Except for the fact, however, that one member of this group, ergosterol, is converted by the action of ultra-violet light into a resinous substance of high antirachitic activity, we know nothing at present. Not only is the nature of the intramolecular change induced by light unknown, but also other important questions remain unanswered, such as the optimum condition for the production of the vitamin, and the amount as well as the particular wave-length of radiant energy required to activate ergosterol. Nor do we yet know in exact figures what quantity of the vitamin so produced is required for the normal development of an animal of a particular species. We only know that the absolute quantity required of the pure substance must be very small, and that excess is apparently innocuous.

It is evident that the solution of these problems requires the collaboration of the biochemist and the physicist, especially in a study of the relationship of induced antirachitic activity in ergosterol to the latter's ultra-violet absorption spectrum. In this connexion it becomes necessary, in view of the tendency of some recent physical work on the subject, to point out that the problem of rickets—i.e., defective calcification in the growing child or animal—is essentially a biological one and, as such, can only be experimentally attacked and finally decided by animal experiment. Conclusions, unsupported by animal tests, drawn from the evidence of purely physical phenomena alone, such as measurements of ultra-violet absorption spectra, may be very misleading, as will be shown later. The spectroscope has afforded valuable confirmatory evidence, although by itself inconclusive, in the previous work on the nature of the vitamin's precursor (i.e., ergosterol), and will no doubt still be useful in further work on the isolation of the vitamin itself. Until this object has been achieved, however, the presence as well as the amount of an antirachitic substance can only be ascertained by the animal test.

When we established last year the fundamental fact that ergosterol is rendered highly antirachitic by irradiation,[1] we did not determine quantitatively the limit of its activity, and even in the subsequent joint work with Windaus, reported in THE LANCET,[2]

* These facts raise again the question of nomenclature; irradiated ergosterol is nitrogen-free and not an "amine." It has even been argued that it may not belong to the group of "accessory food factors" or vitamins at all, since ergosterol may possibly be synthesised by the body, as is cholesterol, and subsequently be activated by sunlight. In view of the historical development of the subject, however, it seems desirable to retain the name vitamin D until the time, probably not distant, when it can be definitely replaced by a more precise term, expressing its constitution.

we had only reached 1/250 mg. per diem of irradiated ergosterol as the lowest daily dose then tested on the rat. Further work [3] has now shown that the limiting prophylactic and curative dose falls into the surprisingly low region of from 1/10,000–1/20,000 mg. According to the results of Miss K. H. Coward, D.Sc., which she kindly allows us to quote, the calcifying effect of a specimen of irradiated ergosterol, prepared by ourselves, can still be demonstrated even with a dose of 1/100,000 mg. per diem by means of the "line test." The results of the animal experiments have been fully confirmed by the clinical experience so far reported. Human rickets is rapidly cured by doses of 2–4 mg. of irradiated ergosterol per diem,[4 F 6] the rapidity of the cure exceeding, in the opinion of two observers, that achieved by cod-liver oil or direct irradiation.

Optimum Conditions.

Our first object, in continuation of this work, was to establish the conditions for the maximum production of vitamin D, when the ultra-violet radiations of the mercury-vapour lamp serve as a source of energy. A study of the time factor was made in the first instance by exposing 0·1 per cent. solutions of ergosterol in pure ether or alcohol for periods of from 30 minutes to four hours. The distance from the lamp was 20 cm. in each case. The effect of a longer exposure was not investigated in this series, since it is established that vitamin D is destroyed by prolonged irradiation. We have already reported that the typical absorption band of ergosterol gradually disappears on irradiation and that the precipitability of the product by digitonin decreases pari passu. On the assumption that the gradual disappearance of ergosterol during irradiation might serve as an index for the formation of vitamin D, we determined the amount of ergosterol remaining unchanged after these periods. The limited supply of pure ergosterol at our disposal prevented us from using the gravimetric digitonin method, and we therefore worked out a roughly quantitative method, depending on the determination of the dilution necessary to produce a just visible precipitate with digitonin. The minimum antirachitic dose of the various reaction products was determined by the animal experiment, using the technique previously described.

The results of a typical experiment are given in the following table:—

Time of exposure in minutes.	Solvent.	Appearance of residue.	Unchanged ergosterol.	Minimum protective dose per diem.
				mg.
30	Ether	White, crystalline.	90 per cent.	1/10,000
120	„	White, partially crystalline.	40 „	„
150	Alcohol	„ „	—	„
240	Ether	Yellowish, resinous.	10 per cent.	„

The surprising results of the animal tests prove conclusively (1) that under the above conditions the maximum amount of antirachitic activity is produced by irradiation for half an hour, or possibly less,† by the mercury-vapour lamp; (2) that prolonged irradiation—i.e., four hours—produces the same yield as a short exposure of 30 minutes; and (3) that the antirachitic activity of the reaction products does not increase pari passu with the disappearance of ergosterol, but remains constant.

This series of animal tests furnishes a striking experimental contradiction of the theoretical conclusions reached on the basis of spectroscopic observations only. It has been found that on irradiation of ergosterol a new ultra-violet absorption band makes its appearance, extending over the region 230–260 μμ, with a maximum at 247 μμ. This band has been assumed to be characteristic for vitamin D by Pohl [7] and Morton, Heilbron, and Kamm.[8] Without the evidence of animal experiments the latter authors conclude from their measurements that "anything approaching a satisfactory yield in the reaction requires prolonged irradiation" and "that the mercury-vapour lamp is unsuitable for this particular photochemical reaction." Both conclusions, which were made with reference to the industrial preparation of the product, are not in agreement with the results of the animal experiment. Whilst we are not concerned with the obviously important question of the most economical source of ultra-violet light suitable for industrial purposes, it may be said that no higher activity, as directly measured in animal experiment, has as yet been reported by the use of any other source (metallic sparks, &c.) than that described by us and obtained with the mercury-vapour lamp.

Various possibilities present themselves in explanation of the unexpected result revealed by the biological test. It may be due to the complexity of the reaction, which does not stop at the stage of vitamin formation, but proceeds further to its rapid destruction. The question whether a state is reached at which the two reactions, ergosterol—>active substance and active substance—>inactive products, proceed at equal rates, so that the activity remains constant till ergosterol is exhausted, is now under investigation. On the other hand, the possibility is not altogether excluded that the effect may be due to an impurity contained in ergosterol and identical with the one shown to be the cause of the induced activity of cholesterol. The position may be even more complex; both possibilities may exist together.

We have so far been unable to find any evidence for the presence of such an impurity in ergosterol. It must, however, be remembered that the present methods of purification are merely physical ones, such as are known to be inefficient in the purification of cholesterol. Unfortunately the chemical methods which helped us in the case of cholesterol (preparation of the dibromide, &c.) cannot be applied to ergosterol, since they lead to the destruction of this more labile molecule. We tested for the presence of an impurity in the first instance by a fractional recrystallisation of the acetate of ergosterol. We established the interesting fact that both ergosterol acetate and benzoate can be activated to the same degree as ergosterol itself. (This fact seems to show incidentally that the hydroxyl group is not concerned in the molecular change induced by ultra-violet light.) For the purpose of the fractionation experiment we started from the mixture of sterols (M.P. 154°), as it is obtained from ergot. According to Tanret [9] this contains besides ergosterol about 10 per cent. of another sterol, fungisterol. The absorption spectrum of the "crude" ergosterol was found to be identical with that of the purest ergosterol at our disposal, and its antirachitic activity after irradiation reached the usual high figure of 1/10,000–1/20,000 mg. Although we have not yet succeeded in preparing a fraction representing absolutely pure fungisterol acetate according to Tanret (M.P. 158°, $[\alpha]_D = -15{\cdot}9$), we were unable to detect any difference in the activity of the various irradiated fractions.

We further attempted to remove the supposed impurity by converting it into vitamin D by irradiation, and recovering the unchanged ergosterol. The partially crystalline product remaining after irradiation and removal of the ether was treated repeatedly with warm petrol, in which vitamin D and other reaction products are easily soluble, whilst ergosterol is relatively insoluble. The perfectly white product was recrystallised from 96 per cent. alcohol and showed the same melting-point (160–162°) and the same characteristic absorption spectrum as the starting product. We are continuing this experiment on a larger scale, controlled by animal tests, and subjecting the product repeatedly to irradiation and recrystallisation.

Failing any evidence of the presence of an impurity in ergosterol, which might act as the parent substance of the vitamin, we think that it is proper to adopt, at least provisionally, the view above indicated, that a

† It may be stated that an exposure of ten minutes failed to produce the maximum potency.

highly complex reaction results from the action on ergosterol itself of ultra-violet light, from any source containing radiations in the region of 320 μμ–230 μμ. This is all the more likely as it is known that vitamin D is a photochemically unstable substance, and since we are still in ignorance of the actual wave-lengths concerned in its production and destruction respectively. It is justifiable to assume, from such knowledge as we possess, that the mercury-vapour lamp emits radiations exerting both functions. It seems that the production of the active substance rapidly reaches a maximum, and that afterwards its destruction proceeds at the same rate as its formation, the exhaustion of the available ergosterol leading to its final disappearance. A solution of this problem should be possible by a systematic investigation, controlled by the animal test, of the effect on ergosterol of monochromatic radiations of known wave-lengths. This investigation is at present being carried out in this Institute.

Activation by Sunlight and Presence in Skin.

In preparation for this work we have investigated whether the activation of ergosterol can be effected by ultra-violet radiations of longer wave-length than those in which the maximum absorption by ergosterol takes place. This question is also of interest, as it has a direct bearing on the explanation suggested for the synthesis of vitamin D by sunlight in the animal organism, and on the consequent prevention or cure of rickets. The absorption spectrum of ergosterol begins approximately at a wave-length 320 μμ and shows three well-marked absorption bands, the strongest being at 280 μμ. It would naturally be expected that light of this wave-length would be particularly effective in activating ergosterol, especially since this band gradually disappears during the formation of vitamin D from ergosterol. On the other hand, sunlight which, after passing through the upper atmosphere, is free from radiations of shorter wave-length than 296 μμ, is known to have curative and preventive action on rickets when acting on the skin. Hume, Lucas, and Smith [10] drew attention to the difficulty which these facts appear to create for the view that the curative effect of direct irradiation of the child or animal by sunlight is due to the formation of vitamin D from ergosterol in the skin.

It may be pointed out, however, that we have previously shown that ordinary cholesterol is rendered antirachitic by exposure to the ultra-violet radiations of summer sunlight, as well as by those of the mercury-vapour lamp. This property was found to be due, according to our subsequent work, to the presence as an impurity in cholesterol, purified by physical means only, of traces of ergosterol or a similar sterol. We have since repeated the experiment with pure ergosterol itself.

A saturated alcoholic solution of the substance, contained in a quartz tube filled with nitrogen, was exposed from 10 A.M.–5 P.M. for four consecutive days (May 23rd–26th). During this period there were three cloudless sunny afternoons. The intensity of the ultra-violet radiations, as measured by the acetone-methylene-blue method of Webster, Hill, and Eidinow, amounted to 16 units. After evaporation of the alcohol the crystalline residue was dissolved in olive oil and its antirachitic activity tested by the methods previously described. It was found that a daily dose of 1/100 mg. of the irradiated product completely protected rats on a rachitogenic diet against rickets.

It is obvious, therefore, that the ultra-violet radiations of relatively longer wave-length contained in sunlight are able to effect the conversion of ergosterol into vitamin D. As in the case of the curative effect of direct irradiation on an animal, a longer exposure to sunlight would be required to induce as high an activity as that obtained by the more powerful artificial light.

In order to test this question still further, we used a screen of vitaglass in connexion with the mercury-vapour lamp. Previous spectroscopic measurements, kindly carried out for us by Dr. R. B. Bourdillon in this Institute, had shown that two sheets of the screen in use only transmitted to an insignificant extent radiations of shorter wave-length than 285 μμ.

The exposures varied from 4–5 hours and ether, alcohol, and petrol were used as solvents. The latter solvent was chosen in order to exclude the possibility of peroxide formation, which might have a deleterious action on the vitamin production. For the same reason, the alcoholic solution was irradiated in a nitrogen atmosphere. No difference in the degree of activation in the different solvents, however, was observed. The results are given in the following table:—

Distance from lamp.	Solvent.	Thickness of screen.	Time of irradiation.	Minimum protective dose.
20 cm.	Ether	4·8 mm.	5 hours	1/10,000 mg.
10 ,,	Alcohol	4·8 ,,	4 ,,	,,
20 ,,	Petrol	2·4 ,,	5 ,,	,,

It will be seen that in all cases the maximum activity was induced, identical with that observed in the previous experiments without the screen. We intend to investigate whether a shorter exposure under these conditions will suffice, and whether the screen will prevent the destruction of the vitamin in a prolonged exposure.

The results already obtained justify the conclusion that the long wave-length ultra-violet radiations of sunlight, and also those which penetrate vitaglass are able to convert ergosterol into a highly active antirachitic substance. It may be assumed that a similar process takes place in the prevention or cure of rickets by exposure of the skin to sunlight. The assumption of Holtz [11] that the skin may change the visible radiations of long wave-length into those of the essential short wave-length is totally unnecessary, in view of the fact that sunlight activates ergosterol.

The fat of the human skin contains a surprisingly large percentage of cholesterol, 13–24 per cent. according to the estimations (digitonin method) of Eckstein and Wile.[12] Since it had been shown [13 14] that the consumption of irradiated skin protects rats against rickets, it became of interest to investigate whether the cholesterol of skin contains ergosterol as an impurity, as do the preparations of cholesterol from all other animal sources. We had an opportunity of testing this question on several hundred grammes of fat obtained from pig's skin, which Dr. H. H. Dale put at our disposal. This was obtained as a by-product from an extract of skin, which Dr. H. C. Hagedorn, of Copenhagen, had kindly prepared for a different purpose. In a preliminary investigation cholesterol was easily isolated by saponification of the fat. The product, crystallising in the typical form from alcohol, possessed the M.P. 147–148° and, on examination of its ultra-violet absorption spectrum, showed an absorption identical with, but more intense than that of cholesterol from brain, described and illustrated in our previous work.[3] Further, it was found that the crystals fluoresced in the light of the mercury-vapour lamp, from which the visible light was screened off by "Wood's glass" and bromine vapour. Under the same conditions cholesterol, purified by way of the dibromide, was non-fluorescent, whilst ergosterol exhibited a strong light-blue fluorescence. It has been shown that vitamin D in irradiated cholesterol can be absorbed from a small area of undamaged skin in sufficient amount to supply the needs of the animal.[10] Taken in conjunction with all the established facts, the demonstration of a substance possessing the same optical properties as ergosterol in the cholesterol of the skin, offers an obvious explanation of the well-known curative effects of sunlight in rickets, the ergosterol in the fat of the skin being converted thereby into vitamin D.

Summary.

The lowest protective dose of vitamin D, induced by irradiation of ergosterol, was found to be 1/10,000–1/20,000 mg. per diem for the rat. The maximum

activity is produced within one half-hour by the radiations of the mercury-vapour lamp (under the conditions described) and remains constant on prolonged irradiation up to four hours. The amount of ergosterol disappearing during the reaction does not stand in relationship to the amount of vitamin present at any given time during this period. In explanation it is suggested that after a short initial period, the formation and destruction of the vitamin proceed at the same rate, so that the activity remains constant till the available ergosterol is exhausted.

Ergosterol is activated by the radiations of sunlight, as well as by the long wave-length radiations of the mercury-vapour lamp. This fact helps to explain the curative effect of sunlight in rickets. The full experimental details of this investigation will be published in full elsewhere.

(FROM OUR OWN CORRESPONDENT.)

Health Reform in the Free State.

THE report of the Committee of Inquiry on National Health Insurance and the Public Medical Services [1] was unfortunate in that it was published in the daily papers on the day before the murder of Mr. Kevin O'Higgins, and therefore attracted little public notice. The first serious comment on it has now appeared in a memorandum adopted last week by the National Association of Insurance Committees. This body expressed its conviction that the only satisfactory solution of the problem of the provision of adequate medical treatment for the working classes and their dependents—whether insured persons or otherwise—lies in the immediate adoption of a national scheme of medical services on a contributory basis, comprehensive in scope and freed from all association with Poor-law administration. It is disappointing that the Committee has not recommended the immediate adoption of such a comprehensive scheme as a practical measure, for not only is the care of the public health one of the first duties of Government, but true national economy lies in the preservation of the working capacity of the people. Economy secured at the expense of the people's health is prodigal waste of national asset. The Association agrees that unless a national scheme embracing insured persons as well as others is immediately adopted, the provision of medical benefit for insured persons is an urgent necessity, but it cannot commend the proposals for medical benefit adumbrated in the final report as satisfactory to insured persons. In its opinion, the very limited advantages which they might confer on certain classes of insured persons are not commensurate with the sacrifices which insured persons generally, as well as their employers, are called upon to make. The Association considers that any scheme of medical benefit to be satisfactory to insured persons must comply with certain essential conditions:—

(*a*) It must be completely dissociated from Poor-law administration.

(*b*) The treatment provided must be thoroughly efficient, which connotes agreement with, and the full coöperation of, the medical profession.

(*c*) Being on a contributory basis, its operation must be open to the free criticism of the persons whom it serves, and it must provide convenient machinery for the investigation of complaints. It must, therefore, be locally administered by bodies on which the contributors, as well as the other interests concerned, are represented.

The Association, as was to be expected, is opposed to the proposal of the Committee of Inquiry that insurance committees should be abolished and their duties transferred to the local authorities. It is satisfactory to find a representative body of this kind coming out strongly in favour of a comprehensive scheme of health reform.

Local Appointments.

By the terms of the Local Appointment Act, 1926, the local authorities were deprived of the power of choosing their officers, except in the case of transfer of existing officers. The nomination to each office is made by a civil service board, the Local Appointments Commissioners, who themselves are guided, in the case of medical appointments, by the advice of a Selection Board, consisting mainly of medical men of repute and good standing. When the Bill was before the Dail it met with considerable opposition, but nevertheless became law. It is only since the Act has begun to work that the members of the local authorities have begun to realise that they have no longer any power of patronage. Many of them are showing their anger by obstructing the working of the Act. One Board of Health, in disgust at failing to secure appointment to a vacant dispensary district for a local candidate, resigned in a body. A few years ago a member of the Board of Health of this same county served a term of imprisonment for having solicited bribes in regard to a dispensary appointment. In many other cases appointments have been delayed and wrangles have taken place between the local authority and the Department of Local Government and Public Health. The law cannot be evaded, however, and the Department is obdurate in insisting on its terms being obeyed.

From another side the work of the Local Appointments Commissioners and the Selection Boards has come in for some criticism which is more worthy of attention. As I understand it, the procedure is approximately as follows. When a vacancy, or more often a group of vacancies, has occurred in the dispensary medical service, an advertisement is issued, applications being invited. Each candidate, with his application, must pay a fee of £1. The list of candidates is submitted to the Selection Board, and in some cases at least the Selection Board has not merely scrutinised the claims and qualifications of the candidates, but has interviewed all the candidates. This appears to be unnecessary and unbusiness-like. There may be 50 or 60 candidates for one or two vacancies, and the Selection Board ought to be able to select, say, half a dozen of the most promising candidates on the documentary evidence submitted. The final choice should only be made after interview. It is grossly unfair to compel a few score candidates who have no chance of selection to travel from England, Wales, or the distant parts of Ireland, without any compensation or grant for expenses. Moreover, the tax on the time of the members of the Selection Boards who, up to the present, are giving their services gratuitously, is greater than need be. These faults are incidental to the system, but they are giving rise to considerable discontent and should be eliminated.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Lower Death-rate.

THE figures recently presented to the Vienna Municipal Board of Health show a remarkable improvement in the health of Vienna since the beginning of the century. In 1900, for instance, the mortality of infants during the first year of life was 178 per 1000, and even in 1913 it stood at 148; whereas in 1925 it had gone down to 80, this level being maintained in 1926. In other words, the decrease during the period has been over 50 per cent., occurring most rapidly since the war, in consequence of the organised care of infants instituted by the municipality. It may be noted also that the general mortality is steadily falling. In 1910–13 the average death-rates was 16·3 per 1000; between 1913 and 1919 it rose to 20·8, and after that went down till it reached its lowest level of 12·2 in 1925. The reduction was secured in spite of the hardships of the post-war period and the persistent unemployment of over 15 per cent. of the population. A death-rate of 12·2 is less than that of Munich, Breslau, and Warsaw (13–14), Paris (14–15), Budapest (16·5), and Rome (17–18), and is bettered only by a few German, Swiss, and English cities (between 9 and 11). Among the particular causes of death tuberculosis takes an important place, the proportion of deaths due to this disease being 20 per cent. in 1914, 28 per cent. in 1916, and 31 per cent. in 1918. This rise was, of course, attributable to the war. In 1920 the proportion still stood at 24 per cent., but in 1925 it fell to 15, which was less than before the war. Though the figure unfortunately went up again slightly in 1926, the systematic campaign against tubercle has done so much to bring down mortality from the disease that steady improvement may be expected in the near future.

Tuberculosis.

At a meeting of German railway doctors, held in Vienna a few days ago, Prof. Roepke read a paper on the principles of the campaign against tuberculosis. After reviewing the famous experiments of Koch he explained the methods of immunisation proposed by Selter (small quantities of living but much weakened bacilli), Friedländer and Calmette (large quantities of non-virulent bacilli), and Langer (dead bacilli). At present, he said, we are not in a position to state which of these methods is best for protecting people who are exposed to infection, and it will be at least 15 or 20 years before we can say definitely how the artificially produced immunity of the infant influences morbidity and mortality in the later years of life. Perhaps too much is expected of artificial immunity, and more stress should be laid on natural immunity acquired from a mild attack of the disease. The objective at present is to enable infants to survive the first two years of life without tuberculosis, for it is during this period that infection is most common and most deadly. With increasing age the natural powers of resistance in the child become capable of combating the bacilli, though they should be assisted by hygienic measures, including light and air. The second very important aim in the campaign is to remove the most serious source of infection—the patient with open tuberculosis. It is the paramount object of all prophylaxis to recognise patients with cavities in the lungs, especially adolescents, as early as possible, and to start regular treatment which will render them innocuous to their surroundings. Statistics show that, so far as Germany is concerned, the fight against tuberculosis is approaching its decisive and final stage; for since 1920 there has been a constant drop in mortality from 2·3 per 1000 in 1918 to less than 1·0 per 1000 at the present time in all towns with a population of 15,000 or over. A larger percentage of the affected persons are nowadays permanently cured, the chronic cases live longer, and fewer patients need be admitted to sanatoriums, all of which facts make it possible to be very hopeful about the ultimate issue. Optimism should be maintained, said Prof. Roepke, in spite of reports from cities such as Vienna, where the mortality is still 2 per 1000, or twice as high as in Germany. And even here, as I have indicated, the death-rate compares very favourably with what it was a few years ago.

Medical Congresses in Vienna.

During the last few years Vienna has been repeatedly selected as a meeting-place for German-speaking medical societies, perhaps because the city offers such good accommodation for large numbers of foreign visitors, and partly because it contains so many interesting medical institutions. In the last week of September the Convention of Surgeons from the Alpine Countries take place here; in the last week of September and the first week of October there will be a meeting of Austrian country practitioners, combined with a fortnight's international post-graduate course in therapeutics; and from Oct. 4th to 7th the Society for the Study of Diseases of Metabolism and of the Alimentary Canal will hold its seventh annual meeting in the city.

Dental Disease and Metabolism.

Dr. Josef Weinmann, in a paper recently read before the Vienna Dental Society, stated that he has observed that a large percentage of the patients who come to the dental clinic suffering from pyorrhœa or complaining of loss of teeth show signs of disturbed metabolism. Assisted by Dr. Liebesny he has investigated all such cases, and has found in over 80 per cent. of them definite diminution in the activity of the pituitary gland. Dr. Liebesny suggested the use of diathermy to increase the internal secretion, and this treatment was employed, together with internal medication (ovarian, thyroid, and pituitary extract). Dr. Weinmann found that the condition of patients receiving this combined treatment improved considerably in the course of some four to eight weeks. All the patients at the dental clinic are now being investigated on these lines, so as to give the new method an extensive trial before it is publicly recommended. The object of making a preliminary report is to induce other clinics to try experiments for themselves on the same lines and inform Dr. Weinmann of their results.

ROYAL MEDICAL BENEVOLENT FUND.

THE following are some additional cases relieved at the last meeting:—

Daughter, aged 56, of M.R.C.S. Eng. who died in 1873. Has lived with widowed sister, helping with domestic duties. Has a temporary allowance from brother-in-law of £5 5*s.* a month and pays £4 5*s.* towards board and room. Now recovering from a severe operation and asks for financial help towards convalescence. Voted £18.

Widow, aged 64, of L.R.C.P. Edin. who died in 1917. No children. Went as a clerk into the district county council, but has had to resign on account of ill-health. Remuneration from post, £118; investments, £4 per annum; health insurance, 7*s.* 6*d.* a week; Freemasons, £2; gift from staff on retirement, £22; friends, £3. Rent and rates, £17 per annum. Voted £26 in quarterly instalments.

Widow, aged 71, of M.R.C.S. Eng. who died in 1897. Only income £76 from investments. Pays 24*s.* a week for bed-sitting and board. Finds it very difficult to meet incidental expenses on such a small income and asked the Fund to help. Voted £18 in quarterly instalments.

Widow, aged 57, of M.D. who died in 1924. Son trained at horticultural college and has purchased a holding and bungalow, but unable to furnish the bungalow. Applicant asked for help towards this expense. £10 voted.

Wife, aged 62, of L.R.C.P. who has been in a mental hospital for 24 years. Has to support herself by cooking and pay 5*s.* a week towards her invalid daughter's board, who lives with married sister. The Fund has paid the husband's life insurance premiums for the past two years and this grant of £9 5*s.* 8*d.* has been renewed. £12 has been sent to the applicant for her own expenses.

Widow, aged 66, of L.R.C.P. who died in 1909. She and her niece have a boarding-house, but owing to the bad weather have been unable to let and are now in arrears for rates. Voted £13 as a special grant.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, 11, Chandos-street, Cavendish-square, London, W.1.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1926 statistics of five county boroughs :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Diarrhœa under 2 years.	Infant mortality.	Maternal mortality from childbirth.
Birmingham (934,300) ..	19·2	11·6	1·10	1·29	2·2	1·7	11·2	73	4·1
Leicester (241,700)	17·0	12·3	1·34	1·63	1·9	1·6	8·5*	77	3·9
Derby (136,600)	19·0	10·9	0·88	1·16	1·6	1·5	7·0	67	2·3
Stockport (125,400) ..	16·1	12·8	0·73	1·44	2·8	—	2·0	82	5·0
Walsall (102,100)	21·1	11·1	1·15	1·16	2·1	1·4	11·6	84	5·1

* Under 1 year only.

Birmingham.

Sir John Robertson mentions that an "important step has been taken during the year in the provision of a site for hospital purposes, which in extent and situation will be sufficient for generations to come, and will enable the question of hospital provision to be put on a proper basis." [1] The Registrar-General's estimate of the population given above is nearly 27,000 less than the local estimate. According to the local estimate the birth-rate becomes 18·7 and the death-rate 11·3. The infant mortality-rate among illegitimate babies was 150, and it is suggested that the Act of 1926 will enable a larger number of these infants to be adopted. Of the 574 illegitimate babies born, 72 were in institutions at the end of the year, 56 died, and 58 removed before a visit was paid. In the case of the remaining 388, the father and mother were living together in 127 cases, the father was making an allowance under an order in 41 and voluntarily in 46 cases, the father was not contributing in 150 cases, and there was no information in 24. In view of the fact that the greatest amount of sickness occurs in February and March, a leaflet was distributed by the health visitors, advising that more time should be spent outside in the winter than in the summer in order to get the maximum advantage from the available sunlight. The wards in Birmingham are divided into central, "middle-ring," and "outer-ring." The death-rate from cancer is fairly equally distributed amongst all three. A leaflet advocating early diagnosis with a view to early operation in the case of cancer of the breast was broadcasted for the second time.

Nursing in the home is provided by 13 district nursing associations, which undertake the nursing of measles, whooping-cough, and pneumonia referred to them by the public health department, at a uniform charge of 10*s.* per case. The health visitors find great difficulty in dealing with the aged poor.

Considerable efforts are being made to improve the condition of the River Tame. The opening of the new refuse utilisation plant at Tyseley in June, 1926, had made it possible to close down five tips. This policy is being extended and the percentage of tons of refuse tipped has been reduced from 34 to 12 in the last four years. Two inspectors are regularly employed in seeing that the closets and drains of courtyards are kept in good order and certain of the courtyards are cleansed periodically by a staff of men. There were 196 excessive emissions of smoke, 93 from boiler fires, 27 from boilers and furnaces, and 76 from metallurgical furnaces. Eighty-eight prosecutions were undertaken and convictions were obtained in every case. The total amount of fines was £172, and it is pointed out that the new Act raises the maximum penalty from £5 to £50. The dirt content of the air was less than the average for the preceding four years. The grit nuisance from the use of inferior fuels with a forced draught, however, is becoming intolerable, and unless more efficient grit-catchers can be devised, action will have to be taken to prevent this method of raising steam.

The houses let in lodgings on the register number 696 and have "always been the bugbear of the public health department." Very inadequately furnished, they are let at exorbitant rents to the thriftless, careless, and poverty-stricken classes.

Notwithstanding the strenuous efforts to overcome the house shortage there is great distress and inconvenience from bad housing among the labouring classes. The houses completed in 1926 numbered 6934, of which 5159 were corporation houses. During the last two years about 4400 have been built towards the arrears of the last 16 years. At the present time old, worn-out houses are allowed to remain, and industries are cramped because they cannot turn out the tenants of the dwellings, which they have purchased for works extensions. The Lower Tower Street unhealthy area was "represented" in May, 1926. It covers 11·66 acres, 10 of which are occupied by dwellings and the remainder by workshops. The dwellings number 517 and house a population of 2703.

Most of the milk-supply is delivered once daily. About half is sterilised homogenised milk supplied in bottles and about a quarter is pasteurised. Particulars are given of the bacterial examination of samples of pasteurised milk. Out of 12 holder pasteurisers the samples from three exceeded the limit of 30,000 bacteria per c.cm., while out of nine flash pasteurisers the samples from four exceeded the permissible limit. The samples from two continuous flow-retarding plants complied with the regulations. There is still a prejudice against the use of pasteurised milk, and firms which hold licences for adequate pasteurisation do not use their licences to the full by selling all their milk in bottles as pasteurised. The public do not in fact realise that most of the milk in Birmingham is treated by heat, and they therefore prefer to buy "loose" milk to *adequately* pasteurised milk in bottles. The city cowsheds house about 1550 cows and among these 21 cases of tuberculosis were found during the year and slaughtered under the order. 811 samples of milk received from outside the city were examined for tubercle, and 8·8 per cent. were found to be infected. As the result of following-up, 63 tuberculous cows were found in outside farms, 44 with advanced tuberculosis and 19 with tuberculous udders. All were dealt with under the order. The Birmingham scheme for securing tubercle-free milch cows included 22 herds and about 696 cows during the year. At the half-yearly testings 71 failed to pass the test, although the majority of the herds are breeding herds. In one breeding herd of approximately 93 cows, 28 failed to pass the test during the year.

Up to the end of 1926 1099 children had been immunised against diphtheria, and since the end of the year the numbers have steadily increased. The use of scarlet fever antitoxin in the hospital appeared to diminish the number of cases with complications, and a full account of the benefits obtained by the surgical treatment of tonsils and adenoids in the promotion of more rapid convalescence of scarlet fever and diphtheria patients and the prevention of return cases is included in the report. The tuberculosis officer, Dr. G. B. Dixon, gives excellent radiograms to illustrate the use of radiography in the differential diagnosis of pulmonary disease, and also photographs showing the progress of cases of lupus

[1] See THE LANCET, 1926, ii., 916.

and abdominal tuberculosis with sinus under light treatment. Encouraging results have been obtained at the venereal diseases centre by the use of diathermy in the treatment of gonorrhœa in the female, and the results obtained by treating acute gonorrhœa in the male with intravenous injections of vaccines "have been extraordinarily good."

Leicester.

Dr. C. Killick Millard reports that his city was visited by a serious outbreak of poliomyelitis. There were 81 cases and seven deaths. Leicester has previously only had sporadic cases of the disease. The first cases occurred early in the summer, and there were 15 cases in August, 37 in September, and 14 in October. Of the 45 patients under 4 years of age, 16 were under 2. Twenty-four cases occurred during the 5–9 age-period, 2 from 10–14, 5 from 15–19, and 5 over 20 years of age. In no instance was more than a single case notified from any one house, and in only three instances was more than one house in a street attacked. The cases were distributed throughout the city and social position appeared to have little influence upon the incidence of the disease. Of the seven fatal cases, four were of the fulminating type and were only ill four, five, and six days. Simultaneously with the outbreak in the city, there was an outbreak in the county of 69 cases, with the same want of evidence of case-to-case infection. Thirty of the cases were treated in hospital, but no members of the hospital staffs developed the disease. The disease was unduly prevalent in the country during 1926, and a chart shows that the chief prevalence in England and Wales was from August to November. Dr. Millard refers to the Edinburgh outbreak of 1910 and to the outbreak in the village of Stoke Rivers in Devon. In the former 62 cases occurred with no multiple cases in houses; in the latter 45 cases occurred within a few days in a village with a population of 119. Almost every house attacked had two or more cases, and most of the cases could be clearly linked up.

The Leicester Cancer Committee have carefully considered the establishment of a free clinic for early diagnosis, and the health committee have advised the council to establish such a clinic.

Diphtheria was unusually prevalent during 1926. There were 366 cases and 37 deaths. The mortality was highest at the age-period 5–9. The disease was widely scattered, and cases occurred at 53 schools. In 88 per cent. of the cases there was no spread of the disease to other members of the household. Dr. Millard thinks that a much stronger case could be made out for immunisation of all children against diphtheria than for vaccination, seeing that the mortality from small-pox for many years has been almost nil. He does not think, however, that Leicester with her past history would be likely to welcome immunisation against diphtheria, as it is somewhat in the experimental stage. As regards inoculation against "common colds," Dr. Millard cites the experiment carried out among the students of Manchester University, from which it appeared that the 138 inoculated students suffered from more colds than the 148 uninoculated.[2] He mentions, however, that the advocates of inoculation show that stock vaccines were used and that freshly prepared vaccines might have been of some value.

The total births were 4119, and the new cases attending the three antenatal clinics numbered 598. Orthopædic cases are already treated at Groby-road Sanatorium. It is proposed to provide there also a ward for poliomyelitis, and to establish an orthopædic treatment clinic in connexion with the school medical department. For the second year since the war the number of new houses has more than provided for the natural increase of the population, and has done something substantial towards overtaking arrears. Dr. Millard stresses the need for more playing grounds for children, especially in the more congested central areas. The ideal is for the presen population in the central parts to be rehoused in th more salubrious outskirts. Under a street improve ment scheme five common lodging-houses, accom modating 323 men, will have to be pulled down, an the present is a good opportunity for the establishmen of a municipal model common lodging-house. Th lectures for stokers have been a success; 49 wer enrolled, and the average attendance was 39.

Four severe cases of puerperal fever were admitte to the sanatorium, and two died. A beginning ha been made with the treatment of uterine sepsis b glycerine drainage.

Derby.

Dr. A. E. Brindley reports that small-pox con tinues to linger. The notified cases during 192 numbered 759, and there were no deaths. The reason given for the continuation of its incidence are failur or delay in notifying, concealment of cases, misse cases, and failure of contacts to accept vaccinatio Dr. Brindley says that no contact vaccinated withi the past 20 years has developed the disease. Oph thalmia neonatorum was slightly more prevalen There were 18 cases notified, of which 9 were treate at home and 9 in hospital. One baby died, 1 wa under treatment at the end of the year, and 1 ha removed. Of the remaining 15, 2 had impaired visio With the existing staff it is impossible to supervis the health of children between 2 years and the ag of entrance to school. A special welfare centre fo children of this age is recommended. There wer 2596 births and 247 expectant mothers visited th antenatal clinic. A large consignment of Newtow apples was found to contain gr. 1/33 of arseni per lb., or three times the amount allowed. Thes apples were twice washed and the amount of arseni was finally reduced to gr. 1/240 per lb. Thirty-seve samples of milk were examined for tubercle, and tw from outside farms were found to be infected. A long list of typical examples of overcrowding is give and also extracts from letters of application for ne corporation houses. The new houses erected durin the year numbered 1444, of which 1286 were part o a municipal housing scheme.

Stockport.

Dr. Nicolas Gebbie records an outbreak of pem phigus neonatorum in June and subsequent month Seven cases occurred in the practice of one midwif and two of these proved fatal. The midwife wen for a holiday and handed over her cases to anothe midwife, and 16 of the 28 cases which occurred wer in the practice of these two midwives. The diseas was made notifiable on Sept. 2nd, and from tha date until March 1st only seven cases were notifie four of which occurred in the practice of a third mid wife. With the exception of the two fatal cases, th type of disease was mild. There is a serious shortag of houses, but no case of dangerous overcrowdin was brought to the notice of the medical officer o health during the year. A table shows that th population during the last ten years has been almos stationary. In September an official representatio of an unhealthy area was made. Out of 12 sample of milk examined for tubercle one was found to b infected. As a result of following up, two cows wer surrendered and destroyed. There were 24 notifica tions of ophthalmia neonatorum, and one baby bor in the municipal maternity hospital lost the sight o an eye. The births numbered 2014. An antenata clinic was opened in 1925 and attended by 61 mother During 1926 130 expectant mothers attended. Dr Gebbie makes an urgent recommendation for th appointment of an assistant medical officer wit special experience in maternity and child welfar work.

Walsall.

Dr. J. A. M. Clark, in drawing attention to th housing shortage and consequent overcrowdin mentions the fact that Walsall is the town with th ninth largest average family (4·61 persons) in Englan and Wales according to the 1921 census. Fou

[2] See THE LANCET, 1927, i., 834.

undred and sixty-eight new houses were built uring the year, 374 by the local authority. The ouncil do their best to encourage graded milk by btaining Grade A and Grade A (tuberculin-tested) ilk for the free issue to mothers. Diphtheria was ery prevalent in the infant department of one chool and 88 children received a full course of immu-ising doses. The privy conversion scheme makes rogress. At the end of the year there were 520 rivies, 10,498 water-closets with a proper flush, 260 water-closets which have to be flushed by a ucket, 85 waste water-closets, and 25 pail-closets. n automatic atmospheric pollution recorder has een installed. During the winter months atmo-pheric impurity is greatest at 7 A.M.; decreases etween 9 and 10 A.M.; is more marked again between and 6 P.M., and decreases after midnight.

Midwives attended 1617 out of the 2104 births 76·8 per cent.) and sent for medical help in 243 cases, f which 84 were in respect of ruptured perineum. Dr. lark describes these figures as startling, and says that oth midwives and medical men called in by them how an equal unwillingness to allow Nature to take er course; there is too great a readiness to adopt nstrumental methods. The inspector of midwives, ho is herself a midwife, conducts the antenatal entre. According to circumstances, the abdomen s examined, the fœtal heart is listened for, pelvic easurements are taken, and the history of previous ifficult labours is recorded; the urine is examined, dvice is given about the hygiene of pregnancy, and he patient is referred through the midwife to her wn doctor when difficulty is anticipated; 130 others attended this centre. In his school report r. Clark draws attention to the bad print of some f the text-books and to school desks of obsolete attern which are too small for the children who se them. Defective vision, spinal curvature, and ound shoulders are possible sequels. He finds that any children have already acquired a squint before ttaining school age. An orthopædic clinic has been stablished, conducted by Mr. G. Percival Mills. here are 214 children on the list between the age f 5 and 16 suffering from crippling defects (including evere heart disease). The open-air school has had nother successful year with an average attendance f 92. A permanent site has now been obtained for he school camp, and for five week-ends and one full eek parties of boys from many schools enjoyed a real oliday under canvas.

PORT SANITARY AUTHORITIES: HULL AND GOOLE.

Dr. W. Allen Daley states that in spite of the coal ispute the trade of the port increased during the ear. Over 12,000 vessels entered, of which 9 per ent. had sanitary defects. There were 490 insanitary (dirty) forecastles and 165 dirty food-lockers; 246 resh-water tanks needed cleaning; 161 water-closets ere choked; and on 41 ships the quarters were erminous. It is difficult to deal with infestation, and is stated that the only remedy is to dismantle he parts affected, burn the old wood on board, and fit. Fumigation with sulphur is effective only hen it is followed by another fumigation 10 or 12 days ter, when the larvæ have hatched out. It was ever necessary to issue statutory notices; hints ere sufficient. Parts of vessels were disinfected ter infectious diseases with 4·5 per cent. of formalin ray or with sulphur. A ship which had landed case of yellow fever on May 8th at Barbados was migated on the same day, again on May 22nd at orfolk, Virginia, and again at Hull on Sept. 8th, is time with formalin, so that no mosquito was kely to survive. No case of cholera, plague, or ellow fever was dealt with; 68 cases of venereal sease were found on board ships on arrival. It is ing discussed whether the duty of killing rats ove high-water mark falls on the city or on the rt sanitary authority; meanwhile 11,333 were counted for in 1926, 8810 of them from ships and from trawlers. Ships from plague-infected ports are required to have rat-guards on their hawsers or to keep themselves three feet off the quay and to cover their hawsers with three feet of fresh tar. Traps are set on board, but not poison baits. Plague was never found among the 632 rats specially examined. There is risk in rat-catching, but overalls and gauntlets are worn, and the fleas on the dead rats are killed by immersion in paraffin. Forty-four vessels were fumigated and some seven rats killed on each. Three pounds of sulphur are burned per 1000 cubic feet, the time of exposure being six hours for the United States and eight for Australia. The port analyst examined 34 samples of water from ships and only 26 were satisfactory. Of the 8357 aliens who arrived, 7283 were transmigrants and were all clean; 259 were certified on account of trachoma, favus, and other infections. Food inspection at Hull is very important, covering 40 per cent. of the imports. Arsenic was found on apples that had been sprayed to prevent growth of the codling moth; it was almost exclusively external. Dealers were advised to brush the stalk and calyx before sale, when there would be no danger if the apples were peeled. The largest amount of arsenic was 0·023 grains per lb.; the amount considered safe is 0·01 gr. Four hundred tons of fruit was condemned and sent to the destructor; the small quantity of meat products condemned was commercially utilised. The report was largely compiled by Dr. E. J. Clark (assistant M.O.H.).

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 3RD, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 111 (last week 166); scarlet fever, 1461; diphtheria, 815; enteric fever, 104; pneumonia, 380; puerperal fever, 40; puerperal pyrexia, 93; cerebro-spinal fever, 4; acute poliomyelitis, 38; acute polio-encephalitis, 3; encephalitis lethargica, 35; continued fever, 1; dysentery, 6; and ophthalmia neonatorum, 92. No case of cholera, plague, or typhus fever was notified during the week.

Deaths.—In the aggregate of great towns, including London, there was 1 death from small-pox, 1 from enteric fever, 13 (1) from measles, 2 (1) from scarlet fever, 18 (5) from whooping-cough, 22 (1) from diphtheria, 52 (11) from diarrhœa and enteritis under two years, and 18 (2) from influenza. The figures in parentheses are those for London itself.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A fortnight's course in medicine, surgery, and the specialties will start at the Westminster Hospital on Sept. 19th. On the same date the Royal National Orthopædic Hospital begins a fortnight's course occupying the whole of each day. From Oct. 3rd to 15th a course in cardiology will be held at the National Hospital for Diseases of the Heart; the daily sessions will be from 10 A.M. to 4 P.M., and entries are strictly limited to 20. From Oct. 3rd, for three weeks, there will be a course at the Central London Throat, Nose, and Ear Hospital; it will be divided into two parts, which may be taken together or separately. The clinical course occupies all day from 9 A.M., whilst the operative surgery class (practical) lasts from 10 to 11.30 A.M. daily. There will also be a practical course in peroral endoscopy. The operative and endoscopy classes are strictly limited. Prof. Louise McIlroy will hold a course in antenatal work at the Royal Free Hospital on Fridays at 5 P.M. from Oct. 7th to 28th. It will be open to ten post-graduates only, and the fee will be £5 5s. At the same hospital, on Wednesdays, at 5.15 P.M., from Oct. 12th to Nov. 2nd, Dr. C. B. Heald will give lectures and demonstrations in electrotherapy. Other courses will be given at the Chelsea Hospital, the Royal Eye Hospital, the London School of Hygiene and Tropical Medicine, and the Paddington Green and Victoria Hospitals for Children. A two months' course in neurology at the National Hospital, Queen-square, also starts on Oct. 3rd, consisting of attendance at the afternoon clinics at the hospitals and certain special lectures. Copies of all syllabuses and of the general course programme are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1, and will be sent regularly to applicants if desired.

Correspondence.

"Audi alteram partem."

POOR-LAW HOSPITALS.

To the Editor of THE LANCET.

SIR,—I read with great interest the excellent letter of Dr. H. J. Bailey in THE LANCET of Sept. 3rd last, concisely pointing out the value of the Poor-law hospitals as they are at present and the extremely important uses to which these institutions might be put. I wish to add a few comments.

As regards medical research, Dr. Bailey mentions the unique and varied material to be found at our large infirmaries. It seems to me that much extremely valuable information regarding certain forms of treatment and the results thereof could be obtained if the necessary statistics were collected from the infirmaries by some central authority such as the Ministry of Health. By this means the large number of cases necessary to obtain statistics of any value could be obtained in a very much shorter period than would be necessary were the cases collected, as is usual at present, by individual effort in voluntary hospitals.

A further point arises in connexion with the use of the Poor-law hospitals for teaching purposes. Would they not be extremely valuable, especially in some of the large provincial towns, for post-graduate instruction? The importance of post-graduate teaching is steadily being recognised, and if the Poor-law hospitals were used for this purpose it would give the post-graduate a teaching school apart from that of the undergraduate.

In order to attain the most efficient treatment of the sick the Poor-law hospitals should be assisted in their process of evolution, which has been very rapid of recent years. A sufficient and efficient medical staff must be provided, and, as Dr. Bailey points out, encouragement offered for work of a professional rather than of an administrative nature.

I am, Sir, yours faithfully,

G. P. B. HUDDY, M.S., F.R.C.S.

Dudley-road Hospital, Birmingham, Sept. 10th, 1927.

A CASE OF CEPHALIC TETANUS.

To the Editor of THE LANCET.

SIR,—The case of cephalic tetanus described by Dr. W. Fletcher and Dr. J. P. Fitzpatrick in THE LANCET of Sept. 10th is, of course, interesting. It had been more interesting had we been told of the treatment adopted. Antitoxin, magnesium sulphate, tracheotomy—any or all of these might have helped, and, with an incubation period of ten days, ought to have helped a little. This type of tetanus was described under the title of "Kopftetanus" in the last century, and was well known when I was a student. A case was described as occurring in Norwich in 1837.

I recall that on entering private practice in Sydney—now over 21 years ago—I saw, within a fortnight, two cases, both in stable-lads, and with an incubation of 14 and 12 days respectively. Both gave histories of facial abrasions, both evidenced facial paresis, and both had modified trismus. Thanks to the teaching of my late clinical lecturer, Dr. W. Camac Wilkinson, I immediately made a diagnosis and exhibited antitoxin; both recovered. An excellent account of this variation of classical tetanus, with many cases similar to that recorded by your contributors, and a full table of references, is to be found in Allbutt and Rolleston's "System of Medicine," 1911, Vol. I., pp. 1039 et seq.

Your contributors say that the condition is very uncommon; it is certainly very rare in any one man's experience, but East of Suez it should ever be in the medical mind.

I am, Sir, yours faithfully,

MACNEILL SIMPSON, M.B., M.Ch. Syd.

Hove, Sussex, Sept. 12th, 1927.

AN EXPLANATION OF THE FORMATION OF WHITE CLOT WITHIN ANEURYSMAL SACS.

To the Editor of THE LANCET.

SIR,—The origin of the white clot found i aneurysmal sacs has always been a mystery to m and the explanations given in text-books have nev been fully satisfactory. The explanations generall given is that the blood clots in the ordinary wa and the corpuscles are subsequently dissolved ou leaving behind a white clot. One other explanatio is that red blood corpuscles are whipped out of th blood by the force of the circulating blood. Regardin the disappearance of the red blood corpuscles fro the clot there never has been reported an invasio of the clot by white blood corpuscles or other phag cytes. Another explanation given is that the re blood corpuscles are dissolved by a ferment, but the is no proof of this. Recently I performed an obliterativ endoaneurysmoraphy of an ileofemoral aneurysm.

The patient was 55 years old, and the duration of th aneurysm was one month. The aneurysm was of the fusifor type, and the extent of the vessel affected was more tha 2 inches. It was the size of an orange, and it pulsate violently. After controlling the common iliac and th external iliac on the same side transperitoneally, and th inferior epigastric in the abdominal wall, the aneurys was incised. The time that elapsed between the control the vessels and the opening of the sac was not more tha five minutes. To my surprise, as soon as I incised the sa clear yellowish fluid escaped, followed by blood. Th amount of this clear yellowish fluid I estimate was abou between 3 to 4 oz. On further opening the sac I foun that it was lined by a yellowish clot about one-eighth an inch thick. This had quite a glistening appearanc The proximal opening was situated about one inch abou the inguinal ligament, and the distal opening was at th bifurcation of the common femoral. The operation whic followed was along the usual lines. The clear yellowis fluid that escaped I take to be blood plasma, and this wa in contact with the sac wall, inasmuch as it escaped soon as the sac was incised. Whenever this plasma clots, fro whatever cause, it will necessarily produce a yellowish clot

While talking about this case a colleague mentione that he had seen a gluteal aneurysm opened unde the impression that it was an abscess. In that cas also clear fluid escaped first, and blood spurted ou afterwards. Surgical aneurysms are not common i Bombay, this being the only case I have had durin three years. I should like to know whether suc clear fluid has been seen to escape on incising aneurysm in the living subject.

The origin of the plasma in the aneurysmal sa may be explained as follows. The pulsation of a aneurysm is admittedly due to ventricular contractio During each diastole the aneurysm shrinks, and durin each systole it expands. During the diastole th aneurysm does not completely empty itself; ther is still a fair amount of blood left in the sac. Eac systole adds to this, and during diastole this adde portion escapes back into the artery by the elasti recoil of the aneurysmal sac and its surrounding The portion of the blood contained within the sa most affected by the entry and the exit of bloo therefore, is that portion which lies towards th centre of the sac and near the opening in the arteria wall. The portion of blood lying in contact wit the sac wall, and also a portion of variable dept from it—namely, that portion of blood which i contained in the sac at the commencement of systole— is merely pushed back and forth by the ingoing an outgoing blood. Naturally the portion that is nex to the opening will be affected more than that portio which is lying against the sac wall. This blood ha only back and forth movement; a certain amount c churning probably occurs in the central portion For practical purposes, then, this blood is out of th circulation; the nearer we approach the sac wa the more it is so. The blood is stagnating with onl a back and forth movement; in stagnant bloo which is not in an easily coagulable condition th corpuscles tend to settle down; the back and fort

movement may even help this settling down owing to the inertia of the corpuscles; after the corpuscles have settled down plasma alone is left, and this plasma shall be more free of corpuscles the nearer it is to the sac wall; it was this plasma which I saw escape from the aneurysm as soon as I incised it and the pale yellow clot found on the wall of the aneurysm sac was derived from this plasma.

I have had diagrams made which illustrate roughly what I think happens within the sac. One shows how the motion diminishes from the centre to the periphery, the short undulations showing marked movement, and longer undulations showing less and less movement of a churning or mixing character. Another shows the condition of the contained blood. My friend, Dr. V. N. Shirodker, kindly drew the diagrams. I am, Sir, yours faithfully,

Bombay, August 20th, 1927. S. R. MOOLGAVKAR.

*** The diagrams were too rough for reproduction, but in essentials illustrate the theory.—ED. L.

REGULAR MEDICAL EXAMINATION.

To the Editor of THE LANCET.

SIR,—The outstanding success of the modern practice of medicine is in the direction of preventive measures based on a wider knowledge of the natural history of disease. This is far more evident in the case of the public health services than in the everyday relation between the individual citizen and the practising physician, even though in the former case the new knowledge is being but imperfectly utilised.

The public continue to regard the doctor as one who heals rather than as one who teaches, and to seek his aid in times of trouble.

We suggest that the great insurance companies, or some other organisation in this country, might help to remedy the deplorable state of the public mind in this respect by arranging regular medical examination facilities for families. A start has been made by prominent insurance companies in the United States (and in our own country by two leading offices), who arrange for the free periodic examination of their policy-holders and thereby encourage the individual to seek at regular intervals medical instruction on the preservation of his health and so provide an invaluable opportunity for the discovery of any early signs of bodily disorder. In 14 years, as the result of regular medical examination, the extension of life amongst its policy-holders has been increased by the Metropolitan Life Insurance Company of New York by nine years, compared with four and a half years among the general population. Defects in habits of living were found in 99 per cent. of those examined.

But since, as a rule, only the adult male members take out life policies, provision requires to be made for the examination of the mothers, adult females, and children.

Such a policy might also cover, above an agreed figure, special medical and surgical expenses incurred by the family. There is a very large family class to whom the expense of expert medical services is very crippling and often prohibitive. Such investigation, advice, and treatment would thus be secured in the early stages of disease. The usual course adopted is to seek such aid as a last resort—generally too late to be of any use.

It would serve also to encourage timely visits to the family practitioner, who is too often called in only when the malady is well established.

We have the honour to be, Sir, yours truly,

WILLIAM MILLIGAN, M.D., J.P.

THE VITAL STATISTICS OF 1926.

THE Registrar-General's review,[1] as is well known, is now issued in three volumes. While this makes for convenience in handling, it involves the awkward necessity for references when Part III. containing the explanatory text appears. The volume here reviewed is Part II., which deals with the chief crude figures relating to population, to marriages and births, deaths being dealt with in Part I. Part II. gives also marriage-rates, birth-rates, death-rates, and infant mortality-rates for each administrative area One table (14 in Part I. and E in Part II.) deals with these matters jointly, and is for convenience printed in both parts. Thus Part II. deals with deaths, but is not the part to be consulted as to deaths. Further medical statistics are given in Part I. already published, and the important text dealing with these and allied matters may be expected later.

The outstanding feature of the vital statistics is the continuing decline of the natural birth-rate. Apart from war years, it was in 1926 the lowest on record, and in fact has now fallen to the war level of 17·8 per 1000 of population. This reduction in the birth-rate has now reached a stage at which the actual number of births in England and Wales is as small as in the year 1860 when the population was only one-half of its present magnitude. This striking reduction in births, which this country shares with many other Western countries, is the most outstanding feature of the social history of the people. It is on a magnitude which is only compensated for to a minor degree by the low general death-rate and the remarkably low rate of infant mortality. The general death-rate was 11·7 per 1000 of population, while the infant deaths per 1000 births were 70.

In preceding comments [2] on our national statistics we have drawn attention to the relatively unfavourable statistics of the north of England, where, for instance, the infant mortality-rate in 1926 was 84, and in Wales 71, as compared with 64 in the Midlands and 58 in the south of England. The explanation of this difference is not to be found chiefly in climatic or in industrial conditions, but more in a lower standard of housing and of methods of life generally. In the rural districts of the north a similar difference is manifest, the infant death-rate in the rural districts of the north being 72, as compared with 50 in the south. We note among the individual sanitary districts in which the infant death-rate was exceptionally high the following: Wokingham 133, Linsdale 138, Hoole 155, St. Ives 140, Harrington 131, Alvaston 167, Newent 118, Lydd 173, Abram 131, Hindley 138, Rainford 172, Trawden 139, Worsley 129. The list might be extended easily, and in regard to some of those named above the data on which the mortality-rates have been calculated are scanty. But making due allowance for this, and remembering the need in each instance to ascertain the death-rates for each area in other years, it is evident that vast differences in infant mortality continue, and that the scope of child welfare work is far from exhausted.

[1] The Registrar-General's Statistical Review of England and Wales for the Year 1926. Tables, Part II., Civil. H.M. Stationery Office. 5*s*.

[2] THE LANCET, August 13th, p. 348.

SEVENOAKS HOSPITAL.—Sir Charles Wakefield, who was a passenger in the train which recently met with disaster at Sevenoaks, has given £1000 to the Sevenoaks and Holmesdale Hospitals, "in recognition of the great services rendered by the medical and receiving staff to the unfortunate victims of the accident."

LONDON HOSPITAL.—Through the generosity of Sir Harry Mallaby-Deeley a new massage and electrical department is to be erected at the London Hospital at an estimated cost of £13,500. Unlike St. Thomas's and St. Bartholomew's, the London Hospital has no coat-of-arms and the committee feel that this must be rectified in view of the importance of the institution.

Obituary.

WILLIAM THELWALL THOMAS, M.B.E., CH.M. LIVERP., F.R.C.S. ENG.

Mr. Thelwall Thomas, who died suddenly at his home near Liverpool on Sept. 10th, was a surgeon of unusual ability whose talents were used generously on behalf of his patients and his colleagues. On the General Medical Council he represented the University of Liverpool, where he was for many years professor of regional surgery, and his recent re-election to the Council of the Royal College of Surgeons of England testified again to the esteem in which he was held by the profession.

Born at Liverpool in 1865, William Thelwall Thomas was educated at the Liverpool Institute and

MR. THELWALL THOMAS.

[*Photograph by Elliott and Fry, Ltd.*

studied medicine at Glasgow Royal Infirmary and University College, Liverpool. Even as a student his ability was outstanding and at Liverpool he was singled out by Sir William Mitchell Banks to assist him as demonstrator of anatomy. Qualifying in 1886, he served for a time as assistant to a practitioner in Wales, and it was then his intention to enter general practice; but after resident appointments at Liverpool Royal Infirmary he reversed this decision in favour of a surgical career, for surgery at this time was making great advances, and his natural bent was towards operative work. He was elected Holt Scholar in anatomy at University College, Liverpool, in 1887, and shortly afterwards became assistant lecturer and demonstrator in anatomy in the University. In 1890 he took the Fellowship of the Royal College of Surgeons and settled down as a consultant in Hope-street, not attempting to combine surgical work with general practice as was generally done by his contemporaries in the North of England. It was not long before his skill began to win the confidence of medical men in the city. Elected assistant surgeon to the Royal Infirmary in 1892, he soon distinguished himself as a rapid and resourceful operator and as a sound diagnostician, and these qualities, together with tremendous industry and unfailing optimism brought him eventually one of the largest surgica practices in the provinces. This well-merited succes sprang also from his competence as a teache Starting at Liverpool at a time when the few surgeon of the city spent almost all their time in privat work, Thelwall Thomas early took a prominent plac in the work of the medical school. At first he taugh many subjects; later, as the school developed, th field of his activities narrowed. From being lecture in practical surgery he was in 1913 appointed professo of regional surgery in the University, and on retirin from this chair in 1922 became emeritus professo As a teacher, he was both admired and liked. Hi manner was direct and genial and his relation with students were always friendly.

In 1907 Mr. Thomas became full surgeon to th Royal Infirmary, and he retired from the hospita staff as consulting surgeon only two years ago. I 1909 he was given the honorary degree of Master o Surgery by the University, and when the Britis Medical Association went to Liverpool in 1912 h was appointed general secretary of the meetin presiding over the Section of Surgery in the followin year when the Association met at Brighton. In 192 he was elected a Councillor of the Royal College o Surgeons of England, and at the beginning of las year he succeeded to the late Dr. Richard Caton seat on the General Medical Council. With S Berkeley Moynihan, Sir Robert Jones, and Sir Harol Stiles, Thelwall Thomas was one of the founders o the Chirurgical Club, whose excellent object was t travel and see the work of other surgeons. Especiall as an example, this club has borne much good frui He was a writer on many topics, including hospita administration and finance, and continued his co tributions to the literature of surgery over man years. During 1918–19 he held office as President o the Liverpool Medical Institution.

We have received the following appreciation fro Mr. Frank Jeans:—

"Thelwall Thomas was above all the doctor surgeon. He used to say he was the first in Liverpo to 'toe the line.' This meant that in the transitio period, when Liverpool was to change from being large town in which one or two men with a reputatio for surgery could in addition to general work carr the surgery of the town and half a dozen counties o their backs, to being a big centre of medical educatio which could support its pure consultants by th dozen, Thelwall Thomas by his courage and acume gave the impetus. He had an exceptional chance bu it is only fair to say that he had more—th exceptional ability to seize it and thus become for a allotted span the leading surgeon of the city. H was delightful to students and very human to patient and his sincerity made an acquired bedside manne unnecessary. He said his certainty of diagnosis wa acquired by the coaching he had to do in his earl days in order to enter the ranks of the consultant He certainly realised that dogmatism was practicall a necessity in a consultant who is called in to decid And the tremendous faith instilled into his patient was because he was so sure of himself. He was a illustration of Bland-Sutton's view that most goo surgeons are quick. Thomas was both quick a making up his mind, which was volcanic in its powe of seeing the kernel of any question and quick i executive and operative power. Brimful of energ and with an immense capacity for work his servic in holding the medical school together during th war were perhaps not fully appreciated. Only serious illness just before the war prevented hi from going overseas.

"When one has known a man as a teacher, colleagu and a friend for a quarter of a century it is difficult t separate one's affection for the man from one admiration for him as an artist, but of the tw surgeons who were privileged to be associated wit him as juniors neither will yield to the other i admiration of Thelwall Thomas as a chief. He die

as he would have wished and as he had lived and worked—quickly. He had few hobbies except of an intellectual and indoor nature, and as his main interest was surgery one wondered what he would do if ever, as seemed unlikely, he were to retire. The problem has been solved by a higher and perhaps kindlier hand."

Mr. Thomas married Miss Anabel Spence, daughter of the late Mr. Alexander Spence, of Aberdeen. She died two months ago after a long illness, and there is no family.

JOHN JOHNSTON, M.D. EDIN.

THE death is announced from Blackpool of Dr. John Johnston, who was for many years a practitioner in Bolton and was at one time president of the Bolton and District Medical Society. Born at Annan in Dumfriesshire 74 years ago, he got his early schooling at the Annan Academy and then went on to the University of Edinburgh, where he graduated in 1874. In the same year he was appointed house surgeon to the West Bromwich District Hospital, and after a further period as resident medical officer at the Birmingham and Midland Hospital for Sick Children, proceeded to the M.D. degree with honours and settled in Bolton. Here he soon had a large practice; he joined the honorary staff of the Bolton Infirmary and was widely recognised as a capable surgeon. Outside his medical work he directed his attention especially to the training of railwaymen in ambulance work, and the usefulness of his teaching was recognised by his being made an honorary associate of the Order of St. John of Jerusalem with the award of a gold medal for long service. In addition, Dr. Johnston held the King George Coronation Medal and a special badge given in recognition of two years' war service as medical officer at Queen Mary's Military Hospital, Whalley, and two years service at Townleys Hospitals, Bolton. Nine years ago he gave up practice and went to live in retirement at Bispham, Blackpool. He was now able to give more time to the literary work which had largely filled his leisure for many years, and he was elected president of the Blackpool Literary and Scientific Society. Amongst his works, which are chiefly poetical, is one describing a visit which he paid to Walt Whitman in 1890. He also wrote accounts of travels in Egypt and Palestine. A memorial service to Dr. Johnston was held at Blackpool on Sept. 5th, and he was buried at Annan on the following day. He leaves a widow.

CUTHBERT CHAPMAN GIBBES, M.D. ABERD., M.R.C.P. LOND., D.P.H.

THE death is announced on August 24th of Dr. C. C. Gibbes, consulting physician to the National Hospital for Diseases of the Heart, at the age of 77. He was the son of Heneage Gibbes, M.D., and received his education at Wimborne Grammar School, the University of Aberdeen, and Westminster Hospital. As soon as he had taken a medical degree he went out to Jamaica for a year as resident medical officer of Kingston Hospital, and on returning to England he took up a similar appointment at the East Devon and South Cornwall Hospital. During the years that followed he gained wide experience as surgeon to the London and South-Western Railway, medical superintendent of Tolworth Hospital for Infectious Diseases, and clinical assistant at Brompton Hospital. On joining the medical staff of the National Hospital in 1897 he set up in consultant practice in London and contributed numerous papers on cardiology to medical journals, including an account of collective investigations of 11,000 recruits with doubtful cardiac conditions. After the war he was appointed consulting cardiologist to the Ministry of Pensions for East Hampshire and the Isle of Wight. Dr. Gibbes's principal recreation was botany, and he was a Fellow of both the Linnean Society and the Chemical Society.

WILLIAM DAVID ADAMS, M.B., C.M. EDIN.

Dr. W. D. Adams, who died on August 28th, was a well-known practitioner in South Norfolk and was medical officer for the Kenninghall district, and for the Thetford and Wayland Unions. Fifty-eight years of age, he was the son of the Rev. David Laird Adams, professor of Hebrew and Oriental languages in the University of Edinburgh. He was educated at George Watson's College, Edinburgh, and after taking an Arts degree at the University, began the study of medicine, winning the Thomson Bursary. On graduation in 1894 he passed into the Navy and served for several years at Haslar and at sea, but in 1899 he left the Service and settled in private practice at Kenninghall. Dr. Adams married the daughter of Mr. P. K. Blofield, of Quidenham, and she survives him with three daughters and a son. His brother is Dr. H. F. W. Adams, of Cirencester.

EDITH NEILD, M.B. LOND., L.R.C.P. EDIN.

Miss Edith Neild died on August 29th at Hartfield after a long period of poor health. Born at Plymouth 53 years ago, she was the eldest daughter of the late Dr. Frederick Neild, and went to Tunbridge Wells with her parents at an early age. She received her medical education at the School of Medicine for Women at Edinburgh and qualified in 1898. For a time she was connected with the London Homœopathic Hospital, but later returned to Tunbridge Wells to help with her father's practice. It was not long, however, before she acquired a practice of her own, and her services were greatly in demand. Like her father, Dr. Neild was a member of the Society of Friends and was known to a large circle outside her own neighbourhood. Her character commanded both respect and affection, and her retirement last June was greatly regretted. For over 26 years she was physician to the Tunbridge Wells Homœopathic Hospital.

Medical News.

OPENING OF THE MEDICAL SCHOOLS: ANNUAL DINNERS.—The following arrangements are announced by medical schools in London:—

London Hospital.—The Old Students' Dinner will be held at the Trocadero Restaurant, Piccadilly Circus, London, on Thursday, Oct. 20th at 7.30 for 8 P.M. Dr. Angus Kennedy will take the chair.

St. Bartholomew's Hospital.—The Old Students' Annual Dinner will be held on Monday, Oct. 3rd, at 7 for 7.30 P.M., in the Great Hall of the Hospital. Dr. Morley Fletcher will take the chair.

St. George's Hospital.—Sir Humphry Rolleston will deliver the introductory address at the hospital on Oct. 1st.

St. Mary's Hospital.—The annual dinner of past and present students will be held at the Connaught Rooms, Great Queen-street, on Saturday, Oct. 1st, at 7 P.M.

St. Thomas's Hospital.—The annual dinner of old students will be held on Friday, Oct. 28th, at 7.30 for 8 P.M., at the hospital. Sir Charles Ballance will preside.

Middlesex Hospital Medical School.—The winter session will open on Tuesday, Oct. 4th. An introductory address entitled the Paths to the Stars, will be delivered at 3 P.M. at the Queen's Hall by Mr. Victor Bonney, after which the prizes gained during the previous year will be distributed by Sir Charles Sargant, Lord Justice of Appeal.—The annual dinner will be held the same evening at 7 for 7.30 P.M., at the Savoy Hotel (Embankment entrance). Mr. Somerville Hastings will take the chair. Those wishing to be present at the dinner should communicate as soon as possible with the Secretary to the Council of the Medical School.

University College Hospital.—The annual dinner of past and present students will be held on Friday, Oct. 14th, at 7 P.M., at the Hotel Cecil. Sir George Blacker will take the chair.

Westminster Hospital Medical School.—The inaugural address will be given in the Board Room of the hospital on Monday, Oct. 3rd, at 3 P.M., by Dr. E. W. Ainley Walker,

Dean of the School of Medicine, University of Oxford.—The annual dinner of past and present students will be held at the Royal Adelaide Gallery, Gatti's Restaurant, Strand, on Saturday, Oct. 1st, at 7 P.M. Dr. de Souza will preside.

THE Lister Centenary Exhibition at the Wellcome Historical Medical Museum, 54A, Wigmore-street, will be closed on Oct. 1st. The Museum is open to visitors as follows: Monday to Friday, from 9.30 to 5.30; Saturdays, 9.30 to 1; Sundays, closed.

CONFERENCE OF GAS INDUSTRY.—Sir Russell Bencraft, M.R.C.S., will preside over the sixteenth annual conference of the British Commercial Gas Association, which will be held at Southampton from Oct. 3rd to 5th. Sir Bruce Bruce-Porter, M.D., will give an address entitled New Health: The Importance of Health in Industry.

HEALTH WEEK.—This year Health Week will be celebrated from Oct. 2nd to 8th, its object being to bring home to every man and woman in this country the importance of health and their personal responsibility for safeguarding it. The dominant idea will be "Self Help in Health." Particulars may be had from the Secretary of the Royal Sanitary Institute at 90, Buckingham Palace-road, London, S.W. 1.

SOCIETY OF APOTHECARIES OF LONDON.—The Court of Assistants has adopted the report of the Examinations Committee recommending the institution of a diploma indicating specialised knowledge of the subjects of antenatal care, midwifery, and infant welfare, and steps are being taken to institute the examinations at an early date. They will be open to registered medical practitioners, and further particulars will be published later.

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES.—In the Michaelmas term courses of lectures will be given by Prof. Alexander on Value (Truth, Goodness, Beauty); by Mr. John Hobson on Economics in Relation to Ethics; by Prof. Leonard Russell on the Approach to Philosophy; by Mr. S. E. Hooper (Director of Studies) on the Introduction to Philosophy; and by Dr. William Brown on Psychology. In the Lent term Mr. Bertrand Russell will lecture on the Philosophy of Physics and Dr. Morris Ginsberg on Social Psychology. In the summer term Prof. Clement Webb will give a course of four lectures on the Philosophy of Religion, and Prof. C. Lloyd Morgan a course of six lectures on Mind in Nature. A full syllabus can be had from the Director of Studies, 88, Kingsway, London, W.C. 2.

Appointments.

BELAM, F. A., M.D. Liverp., D.P.H., has been appointed Medical Officer of Health for Guildford Borough and Guildford Rural District, and Medical Officer to the Guildford, Godalming, and Woking Joint Hospital Board.

KING, P. A. H., M.B., Ch.B. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Holt District of the county of Norfolk.

Vacancies.

For further information refer to the advertisement columns.

Alton, Hants, Lord Mayor Treloar Cripples' Hospital.—2nd Asst. Res. M.O. £300.

Brighton, New Sussex Hospital, Windlesham-road.—H.S. £50.

Brighton, Royal Sussex County Hospital.—H.S. £150. Also Hon. Surg. Clin. Asst., Hon. Clin. Asst. to Ophth. Dept., and Hon. Med. Clin. Asst.

Bristol Education Committee.—Asst. Sch. M.O. £600.

Cambridge, Addenbrooke's Hospital.—Cas. O. and Res. Anæs. At rate of £130.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. At rate of £100 and £50 respectively.

Dumfries, Crichton Royal Mental Hospital.—Asst. P. £350.

Dundee Royal Infirmary.—Asst. S.

Evelina Hospital for Children, Southwark, S.E.—Two H.P.'s. Each at rate of £120.

Freetown, Sierra Leone, Liverpool School of Tropical Medicine Laboratory.—Two Research Assts. Each £600.

Halifax Royal Infirmary.—Third H.S. At rate of £100.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each £50.

Ipswich, East Suffolk and Ipswich Hospital.—Pathologist. £650.

Jersey General Hospital and Poor-Law Infirmary.—Res. M.O. £200.

King's College Hospital, Denmark Hill, S.E.—Clin. Assts., Sen. Med. and Surg. Registrars and Sambrooke Med., &c., Reg.

Leeds City.—Asst. Clin. Tuberculosis O. £600.

London Hospital, E.—Asst. P. Also 1st Asst. and Reg. to one of the Med. Firms, and 1st Asst. and Reg. to one of the five Surg. Firms. Each £300.

London Jewish Hospital, Stepney Green, E.—Hon. M.O. for Dept. for Dis. of Skin. Also Hon. Asst. S. for Dis. of Eye.

Macclesfield, Parkside Mental Hospital.—Res. Clin. Asst. £7

Manor House Hospital, Golders Green, N.W.—H.S. At rate £200.

Middlesex Hospital Medical School, London, W.—2nd Demonstrator for the Dept. of Physiology.

Miller General Hospital for South-East London, Greenwich-road S.E.—H.P. £125.

Mount Vernon Hospital, Northwood, Middlesex.—Anæsthetist.

Newcastle-upon-Tyne Hospital for Sick Children.—Jun. H.S. At rate of £100.

Otago University and Dunedin Hospital, New Zealand.—Sen. Res. Surg. O. £500.

Oxford, Wingfield Orthopædic Hospital.—Res. Surg. O. and H.S. At rate of £200 and £150 respectively.

Prince of Wales's General Hospital, Tottenham, N.—H.S.'s and H.P.'s. At rate of £120 and £90 respectively.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Two H.P.'s. Each at rate of £100.

Rotherham Hospital.—H.P. £180.

Royal Northern Hospital, Holloway, N.—Anæsthetist. £10 10

Royal Westminster Ophthalmic Hospital, King William-street W.C.—Asst. H.S.

St. Albans, Herts, County Mental Hospital, Hill End.—Pathologist and Asst. M.O. £450–£500.

St. George's Hospital, S.W.—Asst. Radiologist. £100.

St. Mary, Islington, Infirmary, Highgate Hill, N.—Asst. M.O. At rate of £350.

St. Marylebone General Dispensary, 30, Marylebone-lane, W.—Hon. S. to Ear, Nose, and Throat Dept.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Anæsthetist. £30.

Seamen's Hospital, Albert Dock, Connaught-road, E.—Ophthalmologist.

Sheffield, Jessop Hospital (Firth) Auxiliary.—Res. M.O £175

Smethwick County Borough.—Asst. M.O. and Sch. M.O. £600

South Shields, Horton Poor-Law Institution and Cleadon Children Homes.—Asst. Res. M.O. £300.

Stoke-on-Trent, North Staffordshire Royal Infirmary, Hartshill.—H.S. £150.

Walthamstow, Wanstead, and Leyton Children's and General Hospital.—Sen. and Jun. Res. H.S.'s. At rate of £150 and £100 respectively.

Watford, Peace Memorial Hospital.—Res. M.O. At rate £150.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Non.-Res. H.S.'s. At rate of £150 and £100 respectively

Westminster Hospital Medical School.—University Readership in Pathology. £800.

Willesden General Hospital.—H.S. At rate of £100.

Woolwich and District War Memorial Hospital, Shooter's Hill S.E.—Hon. Visiting Obstet. S.

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the districts of the Bishop's Waltham, Petersfield, Portsmouth, and Newport and Ryde County Courts (Circuit No. 51). Applications should reach the Private Secretary, Home Office, not later than Oct. 1st.

Births, Marriages, and Deaths

BIRTHS.

LING.—On Sept. 7th, at Welbeck-street, W., the wife of Dr. W. H. G. Mackwood Ling, of Keighley, Yorkshire, of a son

MARRIAGES.

CRAWFORD—SCOULAR.—On Monday, Sept. 5th, at Camphill U.F. Church, Glasgow, James Paterson Crawford, M.D. F.R.F.P.S. Glasg., of Wimbledon, Surrey, to Margaret Muriel, only daughter of Mr. and Mrs. Gavin Scoular, Kilmarnock.

MCCREDIE—GRAY.—On Sept. 7th, at St. Martin-in-the-Fields, London, Peter A. McCredie, M.B., Ch.B., F.R.C.S. Edin., to Rosa Constance, elder daughter of Mr. and Mrs. W. J. Gray, Sedlescombe-road, St. Leonards-on-Sea.

DEATHS.

COX.—On Sept. 7th, at Arden, Cavendish-road, Bowdon, Cheshire, Frederick John William Cox, M.D., in his 70th year.

GLYN-JONES.—On Sept. 9th, at Vancouver, B.C., of cerebral hæmorrhage, Sir William Glyn-Jones, of Gordon-square, W.C.

IVENS.—On Sept. 11th, at Preston-drove, Brighton, Arthur Somers Ivens, M.R.C.S., L.R.C.P., late of Thorpe-le-Soken.

MACVICKER.—On August 30th, at a nursing home in Clifton, of blood poisoning contracted while attending to a patient, Charles George MacVicker, J.P., B.A., M.B., B.Ch., the dearly loved husband of Marian Churchill MacVicker, of Street, Somerset, aged 64.

MORRIS.—On Sept. 6th, Lionel Frederick Morris, L.D.S. R.C.S. Eng.

REYNOLDS.—On Sept. 9th, 1927, at White Lodge, Monken Hadley, Barnet, after a brief illness, Bryan Ellis Reynolds, M.B. Lond., M.R.C.S. Eng., son of the late Edward R. E. Reynolds, M.R.C.S. Eng.

THOMAS.—On Sept. 10th, at Verdala Tower, Allerton, Liverpool, William Thelwall Thomas, F.R.C.S. Eng.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

POINTS SUGGESTED BY RECENT INVESTIGATIONS INTO THE LATE RESULTS OF TREATMENT OF BREAST CANCER.

BY GRETTA M. WARDLE, M.B., CH.B. LEEDS.

IT is of interest and importance to analyse the reasons for the continued high mortality from cancer, in spite of increased facilities for early diagnosis and extensive operative treatment, and to try to estimate whether, as a result of extensive measures to combat it, there is any improvement, even though slight. For such an analysis it is best to take a form of cancer in which early diagnosis and radical treatment hold out some chance of permanent cure, or at any rate, considerable prolongation of life; and cancer of the breast is, in this respect, a favourable form. It is external, would be early noticeable by the patient, is easy of access relatively, and thus is one of the few situations in the body where cancer can be attacked in its early stages, that is, while it is still essentially a local disease.

The following remarks were suggested by a study of the after-histories of breast cancer cases operated on in Manchester and Leeds hospitals. Over 850 cases were dealt with in the course of the investigation, including 200 by Dr. J. Murray, of the Manchester Cancer Committee, nearly all the living patients were questioned and examined personally, while the relatives and friends of those who had not survived were in most instances interrogated.

The Information Required.

The information which is wanted for an exhaustive analysis is as follows:—

1. How many people actually die of cancer of the breast?
2. How many cases dying from cancer of the breast are operated upon? A large number of cases apply for treatment only at a hopelessly late date, or perhaps never at all.
3. Why every case is not operated on? Every case (including those in which there is gross intercurrent organic disease) has an operable stage.

At the present time it is only possible to obtain approximate data for the first two points given above. If accurate figures could be obtained, the value of statistical inquiries as to the results of treatment of breast cancer would be greatly enhanced. Moreover, propaganda should do much to lessen the number of inoperable cases, and it would be of value if its influence could be shown by a definite numerical reduction. Many sources of inquiry would have to be tapped for such an accurate survey of cancer cases, and the co-operation of all branches of the medical profession would be essential.

Deaths from Cancer of the Breast.—We want to know, in a given year, how many of the population, say, of a large town die from cancer of the breast, or are suffering from it at the time of death. This would be easy if every case so long was certified as dying of cancer, but the real cause of death does not always appear for various reasons, though the tendency nowadays is certainly much more towards openness where cancer is concerned than it was some years ago. Thus the first essential would be an attempt to get the general practitioner to certify cancer whenever possible, and in cases where he thinks that for some important reason it is inadvisable to certify that the case was one of cancer, he might be requested to notify the condition (in strict confidence without giving the patient's name) to the public health authority. The annual incidence of cancer of the breast would really be of greater value than the mortality, but this could only be obtained by compulsory certification, which at present appears to be out of the question.

Cases Operated On.—Secondly, we want to know how many of those dying of cancer of the breast were operated on and when. This information could always be shown on the death certificate—e.g., "Operation, two years and eight months," or "No operation," as the case might be. This is sometimes done now. There would be inevitable difficulty in obtaining the reason for no operation. One can only hope that the practitioner would be willing to supply the information when approached by the responsible authority.

There are many difficulties also in obtaining an exact return of all cases operated on in a city. Operations may take place in:—1. Voluntary hospitals: to these it is possible to have access for record taking. 2. Poor-law hospitals: to these also access could be obtained. 3. Nursing homes: in these are the private cases, the records of which can only be made by the surgeons themselves; it might be feasible, in a matter of public welfare, to ask them to take a note of the number of breast cases upon which they operate. 4. Some cases are operated upon by general practitioners in the early stages, usually under the impression that the case is one of non-malignant growth. 5. A number of residents may go to another town for operation, but this leakage should be small. 6. A small number may have been operated upon previous to settling in the town; these will appear as operated cases in the death returns.

There are thus six channels through which patients suffering from cancer of the breast may pass for treatment, and if we could command all sources of information the following data could be amalgamated and, in time, reviewed *qua* the results of treatment and propaganda: (1) the total incidence of cancer of the breast; (2) the reduction of the inevitable mortality in untreated cases by operation; (3) the proportion of cases operated on, showing to what extent advantage was being taken of the facilities available.

The Determination of the Effect of Propaganda: Ignorance of the Laity.

If a more ambitious result were aimed at, such as the determination of the effect of propaganda on the general public and on practitioners, the review would have to extend over some years. It would be interesting to gauge more accurately (1) the effect of propaganda on the general public in inducing them to consult a doctor at an earlier date than hitherto; and (2) the effect of urging the general practitioner to suspect cancer at the very beginning, and to send patients for a confirmatory opinion or operation without delay.

I was amazed to see, in the course of recent investigations undertaken, the amount of ignorance which the laity still display over cancer. The old idea that it is a local manifestation of a general systemic disease persists widely. The idea that a painless condition cannot be cancer is very general. It is widely believed that lumps in the breast can be removed by external applications; hence the valuable time lost by the patient trying various remedies on her own initiative or at the suggestion of a herbalist. There is also a belief that any lump or swelling in the breast occurring about the menopause is a natural accompaniment of that event, and will disappear after a while along with the other signs and symptoms. The dread of cancer and the conviction that it is incurable at any stage and by any means is the most difficult point to combat, because it seems to spring from a definite psychological outlook. Many patients know from the very first that there is something wrong with the breast, which instinct tells them is cancer, but they refuse to see a doctor because they dread having their fears confirmed. Some patients even admit that they have never palpated the breast because they knew from external appearances that something was wrong, but they could not bring themselves to confirm their worst fears by feeling for a lump. This type of mental outlook occurs in the better educated of the hospital class of patient (such as dressmakers, artisans' wives, shop assistants). It would appear that the women of the lowest class neglect to seek treatment through ignorance or carelessness rather than through fear.

The Dangers of Expectant Treatment: Inadequate Surgery.

Instances are still met with where the doctor, thinking that the tumour is simple, a hyperplasia (chronic mastitis) perhaps, but bearing in mind the possibility of cancer, orders expectant treatment, and tells the patients to come up again in three or six months' time. The patient, thinking that the condition is not serious, does not return as instructed, but only after a longer period has elapsed, and then with an advanced growth. The clinical diagnosis of early cancer as opposed to hyperplastic conditions is admittedly almost impossible even for those who have great experience in such cases. Histological examination may reveal a focus of cancer in the seat of hyperplasia. So, if a tumour of the breast is really thought to be innocent, it should be removed widely and examined, and the patient sent to hospital at once if the growth is reported malignant. Judging from some few instances met with in my recent investigations, the medical man may not have had his clinical diagnosis confirmed or refuted after he has removed a breast tumour, with the consequence that a growth recurs at the original site, and by now, probably involves the axillary glands as well, so that a case "favourable" at the outset is turned into a hopeless one. One might even go a step further, and urge that no practitioner without considerable surgical experience should operate on any breast tumour, however simple it may appear clinically, in any woman over the age of 35.

The rule formulated by the Johns Hopkins Hospital is worth bearing in mind—that of all tumours of the breast occurring in women over 35, 75 per cent. are malignant. For the sake of the 75 malignant, the 25 benign should be dealt with only by an experienced hand.

An entirely different attitude must be adopted towards clinically benign tumours in the breast of a woman of 45 than would be adopted towards a similar condition in the breast of a girl of 21. In the investigations of Leeds and Manchester cases it was found that 72 per cent. of the cases which could be definitely classified, had secondaries in the axilla at the time of operation. The universal aim must be to reverse these figures, so that at least 72 per cent. present themselves for operation at the stage when the disease is still confined to the breast. Improvement in the numbers of early cases operated on must be effected primarily by the patients themselves and, to a lesser extent, by the practitioners. In this way the general results of treatment can be definitely improved.

Results of Early Operation.

As a further encouragement to our efforts, I may briefly state here the results of treatment as determined in a recent investigation made by the Manchester Committee on Cancer, the facilities for which were kindly granted by the honorary staff and management of the Royal Infirmary, Manchester. The after-histories of 375 patients operated on for proved cancer of the breast were inquired into, and it was found that of the cases operated on when the disease was still confined to the breast, 72 per cent. are alive at the end of ten years; if cases dying of other causes than cancer are deducted, the survivors number 80 per cent. But of those cases operated on at a stage when the disease has invaded the lymphatic glands, the percentage alive at the end of ten years is only 15. The significance of these findings needs no comment.

THE STANDING NURSE.

To the Editor of THE LANCET.

SIR,—Medical men are aware of the ill-effects of standing at work. Why then, may one ask, are nurses kept perpetually on their feet when so often they might do their work better sitting? For instance, during the application of light to a lupus patch, where accuracy of application is as necessary as that it should be continuous for two consecutive hours, why should the nurse, even in quite swagger homes, be expected to do this work standing beside a couch? Where is the sense of it?

I am led to make these observations by the fact that one of the worst cases of varicose veins in the legs I have seen was in an elderly woman who had been a nurse.

The medical profession—and in this I would include such people as matrons—should lead in these matters and be an example to employers of labour.

I am, Sir, yours faithfully,

T. F. G. MAYER, M.R.C.S.

Burnham, Bucks, Sept. 15th, 1927.

THE SOLDIER'S LIFE IN GERMAN BARRACKS.

A VISIT to a barracks in Germany is reported in the *Military Surgeon* for August. The barracks was four-storied, the offices and stores being on the ground floor, and the dormitories above. These dormitories each held eight men; the walls were papered or brightly coloured with stencilled patterns, the windows had curtains, there were good pictures on the walls, the tables had tablecloths, and with their athletic trophies, books, and flowers the rooms suggested those of undergraduates rather than of soldiers. The men provide all these amenities at their own expense, but are encouraged by authority, as they now spend their evenings at the barracks in reading the books they thus have money to buy. In the rooms were wash-basins, jugs, and slop-pails, and water was laid on in the corridor. The beds were spaced out as in the United States; the men had blue checked sheets, whilst the non-commissioned officers had white. Non-commissioned officers, and men awaiting promotion, had rooms by themselves, or shared with one other; no mention is made of the "Einjähriger" of old, who had better education and served only one year. There were comfortable reading and writing rooms for the companies. Heating was by stoves and ventilation was good. The kitchen and the men's dining rooms were in buildings separate from the dormitories and the food was excellent, being cooked usually by an N.C.O. and his wife. Beer and food were sold in the canteen for "other ranks." The men have four uniforms—a tailor-made full dress uniform and three working suits for drill, gymnastics, and fatigues. The old Prussian half-boot is still preferred, as it has no laces and is readily put on and off, making it easy to rest the feet. Much importance is attached to education which helps the men to get employment on discharge. The largest class, 120 men, was learning English, taught by conversational methods. Officers travel a great deal abroad, achieving this by economising on their mess expenses, which are not to exceed 2*s.* 6*d.* daily. The men also are encouraged to travel in Germany and abroad, and they do.

FLOWERS IN THE SICK ROOM.

To the Editor of THE LANCET.

SIR,—It is, I believe, generally accepted that growing plants give off oxygen and consume CO_2, and one may perhaps assume that cut flowers do the same, to a less extent. In this case both cut flowers and plants in pots would presumably be a useful acquisition to a hospital ward or sick room, and no one seems to contest this view in the case of the daylight hours; but there is a tradition amongst nurses that both flowers and plants should be removed at night, and I have heard it stated in support of this that the chemical interchange above referred to is reversed at night, oxygen being absorbed and CO_2 given off.

Could you or any of your readers kindly tell me what the actual facts are in this matter, and let me know of any references bearing on it?

I am, Sir, yours faithfully,

August 8th, 1927. ABALONE.

*** The facts about the influence of daylight on the respiration of plants are, we believe, as our correspondent states. But it seems very doubtful whether they can in any way explain what is always a point in good nursing practice. No reasonable amount of vegetation could make a perceptible difference in the composition of the air in a well-ventilated sick room. But few people find pleasure in the atmosphere of a room which is heavy with the smell of flowers and plants. A brief contact with it is a refreshing help in sickness and a good morning stimulus is missed if flowers are left in the room all night. At night, too, they are invisible, which halves the delight they can give.—ED. L.

PUBLIC HEALTH IN MOROCCO.

IT is reported that famine and typhus in the region of Agadir are causing anxiety to the French administration in Morocco, but an article by Dr. J. Colombani in the *World's Health* for August makes it clear that such outbreaks are foreseen and can be dealt with. Marshal Lyautey, resident-general from 1912 to 1925, recognised the doctor in a colony as an agent of penetration, pacification, and conciliation, and appointed a medical man as director of health and medical supply. Under him are 45 army doctors, most of them in the frontier zones, and 85 civilians, usually in the towns. These staff the hospitals throughout the Protectorate. Fifteen mobile military medical columns, each with a doctor, carrying drugs, serums, and vaccines, are sent through the less settled districts as arranged by the provincial health officers, and are available in emergencies such as the present. Much attention is given to malaria and typhus; there is an antirabic institute; the health of the ports is safeguarded, and there are four tuberculosis dispensaries with a specialist in charge. Madame Lyautey originated child welfare work in Rabat and it has spread all over the country; antenatal clinics, maternity hospitals, infant clinics, milk stations, creches, and preventoriums against tuberculosis are in full swing, and midwives are being trained.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, Sept. 19th, to SATURDAY, Sept. 24th.—WESTMINSTER HOSPITAL, S.W. Course in Medicine, Surgery, and the Specialties. All day course, consisting of lectures, demonstrations, and operations.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, Great Portland-street, W. Course in Orthopædics. All day, consisting of lectures and clinical demonstrations and operations.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E. Course in Diseases of Children. All day, consisting of lectures, demonstrations, and operations.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, W.C. Course in Ophthalmology. Afternoons, clinical instruction at 2 P.M. Operations at 3 P.M. Special demonstrations at 5 P.M.—BETHLEM ROYAL HOSPITAL, St. George's Fields, S.W. Psychological Medicine, Tuesdays and Saturdays at 11 A.M. Further information from the Secretary, Mayfair 2236.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Sept. 19th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

Remarks
ON
PULMONARY SYPHILIS.*

BY FRANK E. TYLECOTE, M.D., D.P.H. MANCH., F.R.C.P. LOND.,
HONORARY PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; LECTURER IN CLINICAL MEDICINE IN THE VICTORIA UNIVERSITY OF MANCHESTER.

THE very existence of pulmonary syphilis, except in infants, is denied by some authorities. Syphilologists regard it as common, but tuberculosis physicians think it is very rare or non-existent. Yet in this, as in many other things, I hold with Ovid that *in medio tutissimus ibis*.

When Sir James Kingston Fowler published in 1898 the first edition of that most valuable text-book of chest diseases, Fowler and Godlee's "Diseases of the Lungs," he could only find in the museums of the London medical schools 12 examples, two of them doubtful, of acquired syphilis of the lungs. He therefore regarded the condition as a very rare one indeed, but it must be remembered that he was dealing only with post-mortem specimens, and that the Wassermann reaction had not then been discovered.

I describe here 16 cases, 12 of them from my own experience; I have seen many more, but I have never attended a post-mortem on a known case of pulmonary syphilis. This goes to show that any estimate of incidence made on post-mortem results alone is highly fallacious.

There are two specimens of pulmonary syphilis in the Manchester University museum, one from the Delépine and one from the more recent collection. Dr. R. C. Kirkwood (U.S.A.) published last year [1] in the *American Review of Tuberculosis* an article on the diagnosis of pulmonary syphilis,† in which he discusses the association of pulmonary syphilis with pulmonary tubercle, and concludes that it occurs in 1 out of 11 of all sanatorium cases in America. An interesting contrast appears between an intravitam study written since the Wassermann test came into common use and Fowler's post-mortem figures.[2]

A county tuberculosis officer of my acquaintance detected 12 cases in 8000 patients seen by him in eight years—i.e., 0·15 per cent. He agrees with me that the percentage will be much higher when the Wassermann test becomes the rule in all negative sputum cases, as well as in atypical positive sputum cases. I estimate the incidence at about 1 per cent. of the sanatorium cases in this country, and it is interesting to see that two observers in other countries give figures which support this. J. T. Conner did post-mortems on 112 syphilitic cases in America,[3] and found it in 10 per cent.; he excluded tubercle in all of them. Petersen [4] did post-mortems in 88 syphilitic cases in Copenhagen, and found it in 11. The National Council for Combating Venereal Disease (British Social Hygiene Council) stated that syphilis affects 1 in 10 of the hospital population of the country. If this figure and those of Conner and Petersen are accepted, the estimate of 1 per cent. is probably correct.

A classical case was recorded by the late Dr. R. J. M. Buchanan, of Liverpool [5]; she went the round of the Manchester physicians, and was 19 years under observations before he made the correct diagnosis by finding spirochætæ in the sputum. She was known as the "girl with the ducks in her chest." Another case reported by Buchanan was one of the earliest cases of syphilitic lung, in which the effect of antisyphilitic treatment was demonstrated by periodic X ray plates.

Of the 16 cases of whom I have notes, 11 were male and 5 female. The average age of the males was 50·82 years and of the females 47·00. The chief reason for this advanced average age is that fibrosis is the main feature and takes time to develop.

* The substance of a post-graduate lecture delivered at the Manchester Royal Infirmary.

† See abstract in Tubercle of Dec. 1st, 1926.

PATHOLOGICAL CHANGES.

1. *Infantile pulmonary syphilis* has been well investigated and occurs in two forms:—

(*a*) Interstitial or white pneumonia of the fœtus, where the alveolar walls are infiltrated, and the alveoli blocked with desquamating epithelial cells. The condition is incompatible with life for more than a few hours.

(*b*) Gummata alone or combined with (*a*). The children are usually stillborn and exhibit other syphilitic lesions in which spirochætæ are found.

2. *Acquired pulmonary syphilis* has five forms:—

(*a*) Syphilis pulmonum, a combination of areas of fibrosis starting from root or base, possibly with ulcers of trachea, larynx, or bronchi, sometimes with resultant bronchiectatic or gangrenous cavities, with or without gummata (which are rare in adults).

(*b*) Chronic interstitial pneumonia due to syphilis; a generalised condition; a fibroid phthisis in a syphilitic subject; not tuberculous.

(*c*) Syphilitic gummata.

(*d*) Lesions due to deficient blood-supply, the results of syphilitic arterio-sclerosis, with infarcts, pulmonary emboli, serofibrinous pleurisy.

(*e*) A pulmonary arterio-sclerosis with great œdema, described by Sir Leonard Rogers among Bengalese of 20–40 years of age, chiefly females.[6] He believes it to be specific in origin.

The Delépine specimen came from a female, aged 36, and shows fibrous induration largely replacing the tissue of the right lung, in which there are also bronchiectases and overlying chronic pleurisy. The liver is deformed by contraction after gummata, and other small gummata are also seen in both its lobes. The gummatous mass has passed through the diaphragm into the lung, a very good example of the affection of multiple organs with tertiary syphilis. Histological preparations from this specimen show the difference from tubercle of the lung, the peribronchial fibrosis, thickened vessels, and comparative scarcity of giant cells.

SYMPTOMATOLOGY.

Practically all the symptoms and signs of general chest disease occur in pulmonary syphilis. Though the term is usually applied to the tertiary stage, it must not be forgotten that a catarrh of the air passages, with signs of bronchitis, may occur in the secondary stage as an exanthem, possibly with pyrexia, the so-called "syphilitic fever," a somewhat rare condition. Of the symptoms which are outstandingly and unexpectedly prominent in pulmonary syphilis, the first is *dyspnœa*. In some cases it depends on inspiratory obstruction, as when there is tracheal or bronchial stenosis secondary to ulceration, or, more rarely, to pressure from without by a gumma. In most cases it depends on peribronchial fibrosis and sometimes the paroxysms may be asthmatic; this is a possible explanation of the good results of treatment by iodide of potash. As fibrosis takes time to develop it will not be marked in the young. Dyspnœa of more sudden onset may be due to syphilitic myocardial failure.

Hæmoptysis.—Though hæmoptysis only occurred in one of my cases, yet the literature quotes it as common. Those cases in which it has occurred are cases either of ulceration of the trachea or bronchi or of bronchiectasis developing as a result of such ulceration. It is rarely, if ever, fatal, but may recur.

Blood Pressure.—It is not usual in syphilis of the lung to get the lowered pressure customary in tubercle and malignant disease, so a normal or a slightly raised blood pressure is a point in favour of a diagnosis of syphilis.

Bronchiectasis.—Where bronchiectasis has resulted all the bad features of that disease are encountered, such as pyrexia due to retained secretion or to broncho-pneumonia, loss of weight, and general decline. In

the average case of pulmonary syphilis, however, there are widespread physical signs with little or no constitutional disturbance, and no pyrexia, anorexia, or loss of weight. The fitness of some patients in spite of marked lung signs is marvellous.

Distribution of Lesion.—A one-sided distribution in the chest, or hilar or basal rather than apical signs will sometimes suggest the diagnosis, and the radiogram may give the additional information that the spread of the fibrosis, or even of the gummata, is directly along the primary or secondary vessels and bronchi. It may also show marked thickening of the mediastinal shadows, and, as a rule, a heart-shadow differing in shape from that seen in tuberculosis. In chronic cases wrongly diagnosed as tuberculosis ringed shadows and evidences of calcification are absent. Evidence of syphilis in other organs than the lung is most suggestive. In one case, regarded as pure pulmonary tuberculosis, but in which fibrosis was very marked, the absence of the knee-jerk on one side led to the disclosure of a syphilitic history and a beneficial alteration in treatment.

Wassermann Reaction.—It is good practice to do a Wassermann test in all cases with repeatedly negative sputum tests, and in all atypical cases, as mixed tubercle and syphilis of the lung is not uncommon. Where pulmonary syphilis takes the form of a gummatous mediastinal tumour the positive Wassermann indicates a more hopeful diagnosis and antisyphilitic treatment. If pulmonary syphilis is suspected a Wassermann of the cerebro-spinal fluid should be done. If it is negative a provocative injection of novarsenobillon should be given before repeating the process. When X rays show the typical appearances of fibrosis or gumma the patient may give a negative Wassermann as a result of recent treatment. He may not disclose the fact until closely questioned, not knowing that it is important. There are occasional cases of undoubted syphilis in which both blood and spinal fluid Wassermanns are always negative.

FEATURES AIDING DIAGNOSIS.

The following is a general summary of features which have aided diagnosis in my series of cases.

1. Signs of phthisis, but repeated examinations of sputum for tubercle bacilli negative, and guinea-pig inoculations also negative.
2. Improvement in symptoms, especially asthma and dyspnœa, follows potassium iodide given empirically.
3. Signs marked, but history long and condition stationary. On the other hand, there may be no signs, except radiographically.
4. Other organs involved by ? syphilis.
5. Wassermann positive.
6. Recurrent but never fatal hæmoptysis.
7. Site of "TB" lesions unusual, and course abnormal.
8. Mixed TB and syphilis in lungs; TB may heal and sputum be negative, but symptoms—e.g., marked dyspnœa—remain.
9. Spontaneous fractures in patient and in another member of the family.
10. Blood pressure rather too high for tubercle or malignancy.
11. Symptoms typical of a mediastinal tumour, but Wassermann test, the effect of iodide, and the longer course differentiate mediastinal gumma from lymphosarcoma; X rays do not, as a rule, help in treatment.
12. Bronchiectasis, or tracheal or laryngeal stenosis.
13. "TB laryngitis" is never primary, so if this diagnosis is made, and there are no signs of lung disease, syphilis should be suspected unless an X ray shows typical tuberculosis. A syphilitic laryngeal ulcer should heal with potassium iodide, but local and general treatment and tonics may be necessary to complete cure (cf. vicious circle stasis in laryngeal diphtheria followed by ulceration from tube).
14. X rays show fibrosis of a peculiar distribution, with no calcification and no ring shadows, but much mediastinitis, with broadening of mediastinal shadow, and heart-shadow of a different shape. Radiographic peculiarities have, however, still to be worked out.
15. Chest signs, with little or no loss of weight, but marked peculiar anæmic appearance. Absence of the usual pyrexia of tuberculosis of similar severity.
16. Signs of serofibrinous pleurisy; the fluid recurs after repeated tappings, but the patient does not go downhill (cf. recurrent ascites, with stationary condition, due to syphilitic peritonitis or cirrhosis).
17. If histological autopsies were always done the typical appearances of syphilis would be found in many of the cases passed over, naked-eye, as tuberculosis.

TREATMENT.

The drug which gives the most rapid and unexpectedly good results in pulmonary syphilis is potassium iodide. Doses of 5 to 10 gr. thrice daily are often sufficient, but where gummata are present much larger doses are required. Where retention of secretion is giving rise to bronchiectatic cavities, as well as where free secretion is troublesome, Rolleston and C. Ogle[7] have drawn attention to the advantage of combining belladonna with the iodide. I have also found the addition useful when dyspnœa is a prominent symptom, very likely due to some extent to spasm.

The success of treatment in those cases in which there is any element, however slight, of tracheal or bronchial stenosis depends primarily on early diagnosis. There is a grave tendency to cicatricial contraction of scar tissue in these regions. Tracheoscopy and bronchoscopy are of much diagnostic value in doubtful cases.

Tonic treatment is often useful, and includes syrup of the iodide of iron in 1 drachm doses, and arsenic, either by mouth as Fowler's solution 1 to 5 minims, or intravenously as novarsenobillon, in selected cases in which the heart condition is reasonably good. The ferrum tartaratum combined with iodide of potash is also helpful.

Mercury requires more care in its use, but is not, as a rule, contra-indicated so long as the patient is kept under careful observation. On the whole inunction is best, but it may be given in the usual mixture with iodide. At the first sign of stomatitis it should be stopped. Under its use albumin may disappear from the urine in generalised visceral syphilis.

For the more well-to-do patient a course of warm sulphur baths at Aix-la-Chapelle or a voyage to the Canaries may be prescribed with benefit. Not only in those cases in which tubercle and syphilis are combined is benefit derived from fresh air, change of scene, and voyages. Even in the purely syphilitic cases the good results obtained from these measures with the rest which they imply is at times extraordinary.

It is very instructive sometimes when a case of dermatitis fails to heal up completely to see the great benefit derived when antispecific treatment is added to the local treatment already in progress. The same applies to cases of pulmonary tuberculosis which have a specific element. Indeed, temporary improvement may result, even in malignant conditions, from antispecific treatment in specific subjects. It is well known that syphilis is an ætiological factor in cancer of the lip, tongue, &c. I have also used with benefit thyroid gland and "Donovan's solution" in 10 or 15 minim doses. In mixed syphilis and tuberculosis the almost constant peribronchial fibrosis contra-indicates artificial pneumothorax. Complete recovery cannot, as a rule, be promised in syphilitic disease of the lung.

SELECTED CASES.

A synopsis of selected cases is here given:—

1. Male, aged 49. Starch worker. Two years' history of dyspepsia. Now has cough and nausea. Has lost 2 st. in last 18 weeks. No appetite; pale; anæmic. An indefinite resistance in upper part of abdomen. Liver enlarged, but also an indefinite lump palpable, apparently the lower pole of right kidney. Blood and albumin in urine. Signs of bronchitis at right base. Sent for an X ray examination as ? carcinoma stomach. X ray report: "Stomach normal; but lungs show general mottling, as tubercle but mainly basal, apices almost clear; suggest miliary tubercle." We then suggested tubercle of kidney as a possibility, and X ray report came back: "Kidneys normal to X rays; but calcified glands seen in front of sacrum." By this time we had received a strongly positive Wassermann report, also negative reports as to tubercle bacilli in sputum and urine. At no time was there any pyrexia. Novarsenobillon and mercury by inunction were now given, with rapid improvement. Chest signs were limited to rhonchi

over right lower lobe, consonating râles low down at the back on the right side, and slight friction over left border of sternum and precordium. First sign of improvement noted was that the urine cleared up as soon as antispecific treatment began (cf. Sir T. Myles).[5]

2. Female, aged 49, twice married. One child aged 21. Three months' cough. One month pleurisy. Returned from holidays just previously to admission; tired and weak. No previous chest trouble. Admitted as "asthma; getting worse." In coughing fractured third right rib near vertebral end; pleurisy, and later effusion, resulted; 56 oz. removed, clear, straw-coloured. Improving with rest and potassium iodide. No anæmia. Wassermann strongly positive. The indirect benefit a Wassermann may confer is well illustrated by Kirkwood, who relates a case in which as a result of his finding out that a woman had mixed tubercle and syphilis of the lung syphilitic treatment of a hitherto ununited fracture of the femur in her husband was completely successful, firm union resulting.

3. Female, unmarried, aged 56. Admitted as mediastinal tumour, with fluid at right base. This diagnosis was made because she was markedly distressed and cyanosed, with prominent superficial veins on the chest wall, together with mediastinal dullness in front and dullness over right lower lobe. A routine Wassermann was strongly positive, but before we could start any antispecific treatment the pulse-rate shot up, and as tapping the chest showed that the fluid now looked like liquid fæces, she was transferred for operation. She stood this well, and left the hospital much improved. Probably this was a case in which a breaking-down gumma of the liver burst through the diaphragm into the pleural cavity, and in the end the cavity became infected with *Bacillus coli*. Syphilitic treatment followed.

4. Male, aged 48, warehouseman. History of syphilis 15 years ago. Brother died of phthisis 30 years ago. Outstanding feature great dyspnœa, even when at rest. Cough with audible mucous secretion as he talks, yet he calls it a "dry cough." Two attacks of pleurisy, the second in January, 1925, and dyspnœa since. Three negative sputum specimens subsequent to positive ones. Lost flesh after first pleurisy attack, but regained it; losing again this year. A1 for insurance six years ago. Strongly positive Wassermann. Dull right apex and root. Tuberculous appearance. X ray shows broad mediastinal shadow, atypical distribution of involved area, mainly right-sided. Heart shadow unlike that of tuberculosis. Great improvement for a time under iodide, mercury, and later novarsenobillon, but later heart muscle slowly failed.

5. Male, aged 56, a baker. Admitted for great and urgent dyspnœa, with an outside diagnosis of asthma. History of osteomyelitis of right tibia, when aged 15, and of pneumonia a year ago; also of syphilis when aged 30, for which had three years' treatment at a lock hospital. Urine normal. Blood pressure 128/80. Wassermann strongly positive, 1 in 40. Signs of bronchitis and emphysema, with dullness and diminished breath sounds at right apex, and increase in vocal resonance. X ray of chest shows diaphragmatic adhesions on both sides, with hilar shadows stronger than usual. Did well under iodide at first and intensive treatment later on.

[Dr. Tylecote described several other cases, and showed radiograms illustrating various points. He then concluded by thanking Prof. Shaw Dunn, and Drs. W. B. Anderton, A. E. Barclay, W. J. S. Bythell, and J. L. Stewart for assistance in various directions in connexion with the paper.]

SYDNEY HOSPITAL.—This hospital, one of the oldest institutions in Australia, is making an appeal for several thousands a year of additional income. It began its work as along ago as 1788, and from tents and wooden structures has developed into its present fine building, with thoroughly modern equipment. The annual expenditure amounts to more than £100,000, but the receipts unhappily fall considerably short of that sum.

PHIMOSIS AND DYSURIA IN INFANCY.

A CLINICAL INVESTIGATION.

BY A. J. C. HAMILTON, M.B., F.R.C.S. EDIN. & ENG.,
HON. SURGEON, NORTHERN INFIRMARY, INVERNESS; LATE CLINICAL ASSISTANT, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH;
AND
D. S. MIDDLETON, M.B., F.R.C.S. EDIN. & ENG.,
SENIOR CLINICAL ASSISTANT, ROYAL HOSPITAL FOR SICK CHILDREN.

PART I.

AMMONIACAL DERMATITIS OF THE NAPKIN AREA AND ITS RELATIONSHIP TO DYSURIA.

THE question of phimosis and its relationship to circumcision is of considerable importance because of the frequency with which the operation is carried out, and it has appeared to us that this subject has received less consideration than it merits. The following paper is the result of a year's observation of all cases subjected to or recommended for circumcision in the surgical out-patient department of the Royal Hospital for Sick Children, Edinburgh, and constitutes an attempt to analyse this clinical material and review the whole subject. In a series of over 600 cases recommended for circumcision during the year under consideration, the chief complaint has been dysuria in about 53 per cent; 19 per cent. have been sent up because the doctor, nurse, or a neighbour thought that circumcision was necessary. In 12 per cent. an adherent prepuce or a true phimosis was discovered during the examination of a hernia or a hydrocele.

The high incidence of cases in which the symptom complained of was dysuria divides this investigation naturally into two main sections: (1) ammoniacal dermatitis of the napkin area and its relationship to dysuria; (2) the status of circumcision as a surgical procedure.

Our attention was directed to ammoniacal dermatitis of the napkin area and its relationship to dysuria by (1) its frequency (over half of our cases); (2) its persistent tendency to relapse in untreated cases; (3) the obvious incongruity of treating it by the removal of a perfectly lax prepuce which did not seem to be in any way responsible for the pain; (4) the resemblance between the symptoms of dysuria seen in the uncircumcised child and that observed in the meatal ulcer of the circumcised.

The only reference to this subject which we have been able to find in British literature is in John Thomson's [7] "Clinical Study and Treatment of Sick Children," which draws attention to Zahorsky's [8] work on the ammoniacal napkin and its relationship to the occurrence of meatal ulceration. This work attributes to a common cause dysuria, napkin dermatitis, and meatal ulcer, but the treatment recommended is purely empirical in character. The treatment of the various manifestations of ammoniacal irritation was put upon a rational basis in 1921, when Cooke, of St. Louis [3 4] published the results of an exhaustive clinical and experimental investigation, in which he demonstrated the efficacy of antiseptic impregnation of the napkin as a method of treatment. In a later paper Lanman [6] confirmed Cooke's findings.

Clinical Features.

Ammoniacal napkin irritation causing dysuria presents a definite clinical syndrome which may be described under four headings: (1) smell of ammonia; (2) irritation of the napkin area; (3) dysuria; (4) diet.

1. *Smell of Ammonia.*—There is a definite smell of ammonia from the napkins when they are removed if they have been allowed to remain in contact with the child for a short period of time in a wet condition. This is, of course, most marked on removing the morning napkin. Most mothers in this part of the country describe the ammoniacal napkin as "strong," or "irritating to the eyes," without recognising the ammoniacal origin of the odour, while many look upon it as a normal condition. Occasionally one encounters a mother complaining of the ammoniacal odour only, without having noticed

any irritability on the part of the child. It is also not uncommon for a mother to deny indignantly that the napkins smell at all, even though the odour may be easily recognised at several yards distance at the time of examination.

The urine collected directly into a vessel is entirely free from odour, and it should be noted that the odour is the pungent one of fresh ammonia, and is quite distinct from the foul smell of decomposing urine.

2. *Irritation of the Napkin Area.*—This may take the form of an erythematous or of an ulcerative lesion, and we have gradually come to recognise several distinct types: (*a*) simple erythema, (*b*) scaly erythema, (*c*) ulceration, (*d*) severe ulceration, (*e*) preputial dermatitis, (*f*) meatal ulcer.

(*a*) *Simple Erythema.*—A mild blush of the prepuce, scrotum, and inner sides of the thighs.

(*b*) *Scaly Erythema.*—Old-standing cases of the above type where the epidermis becomes thickened and glazed, then cracked and scaly in appearance, finally desquamating, often in large scales.

(*c*) *Ulceration.*—Ulcerative lesions with or without some accompanying erythema, affecting the scrotum and thighs. The "ulcers" commence as bluish-grey moist thickenings of the epidermis. The lesion is, in the absence of secondary infection, confined to the epidermis and therefore heals without scarring.

(*d*) *Severe Ulceration.*—Old-standing and very severe instances of the ulcerative type are not by any means common. In these the lesions have become confluent and bear at first sight a startling superficial resemblance to a widespread phagedæna. The epidermis is moist and thickened over the whole napkin area, and in places assumes a black colour as if undergoing gangrene. The lesion being practically confined to the epidermis, there are no marked toxic symptoms, though the infant may be very much worn out by constant pain and discomfort.

(*e*) *Preputial Dermatitis.*—Excoriation or ulceration affecting mainly the tip of the prepuce and often combined with some degree of irritation elsewhere. This type forms a definite entity by itself. The prepuce presents a somewhat bulbous extremity, which is thickened so as to be almost mushroom-shaped, and is fissured and excoriated. This condition is frequently designated "chronic balanitis," a term which is entirely incorrect and misleading. It is more accurate to refer to the condition as a preputial dermatitis, and this term is employed throughout the article.

The terms "balanitis" and "balano-posthitis" properly imply the presence of an inflammatory condition within the preputial sac. On inspection of the above type (*e*), of excoriated prepuce, however, it is very evident that all thickening and ulceration is not only confined to the free end of the prepuce, but affects an area at and just outside its orifice. On retracting the prepuce, moreover, no signs whatever of inflammation can be seen and the ring of smegma in the coronal sulcus is found to be uninfected. These observations have been confirmed by microscopical examination of prepuces after removal, in which no inflammatory reaction could be seen on the inner surface, the reaction being entirely confined to the outer aspect of the tip of the prepuce. It is not uncommon for the ring of œdema at the tip of the prepuce to prevent retraction, whereas, after the irritation has been cured by adequate treatment, the prepuce retracts with ease. True chronic balanitis is, in our experience, extremely rare in young children.

(*f*) *Meatal Ulcer.*—A lesion analogous to the above, but occurring in the circumcised child. In these cases one finds an ulcerative lesion at the glandular urinary meatus varying from a slight excoriation to an ulcer occupying half the surface of the glans penis. The history usually given is that a "water-blister" formed and then burst, leaving an ulcer which has evinced no tendency to heal. The majority of cases follow circumcision for the last-mentioned type of lesion (*e*). The meatal ulcer, like all ammoniacal lesions, is confined to the epidermis and heals without any scarring. Stricture of the meatus on healing only occurs as the result of infection of the chemically produced ulcer with pyogenic organisms. Despite the statements to the contrary often met with, this is, we think, extremely rare. The meatal ulcer exudes a little serous fluid which dries and forms a crust which may seal the meatus. In addition, the severe pain induced by micturition in these cases may lead to a reflex acute retention of urine, of which condition meatal ulcer is by far the commonest cause in children of this age. The meatal ulcer is the classical ammoniacal lesion in all cases in which the glans penis has been deprived of its normal preputial covering, and we have seen a typical meatal ulcer in a child who had never been circumcised, but who was the subject of a minor degree of glandular hypospadias with a congenitally short, hoodlike prepuce which did not efficiently cover or protect the glans.

3. *Dysuria.*—The child screams and draws up the legs just before and during the act of micturition.

4. *Diet.*—The condition is seen almost exclusively in bottle-fed infants or in children of the napkin-wearing age on a mixed diet. The condition very commonly appears immediately after weaning the child from the breast.

In all the types of napkin irritation due to ammonia one finds that the irritative lesions are most marked on the convex surfaces of the skin folds in the region—that is to say, the portions of skin which come most intimately into contact with the napkin, while the clefts between these folds are relatively unaffected. Adamson [1] has observed, moreover, that erythema is often encountered on the calves of the legs and the heels—that is, on those parts which come into contact with the outer surface of the napkin in the flexed position of the limbs commonly assumed by infants.

Sex.—While we are particularly concerned with the condition as it affects the male child, ammoniacal napkin irritation is also met with in females, but in them, owing to the protected situation of the urethra, it is seldom the cause of dysuria. The condition is said by some, however, to be an almost invariable precursor to the acute pyelitis of the female child.

Age.—The condition occurs most commonly in the first year of life, especially following weaning, whether this be done early or late. If the mother is questioned the onset of a smell of ammonia or of the signs of irritation can in many cases be dated quite definitely from the commencement of bottle-feeding, while the condition is rare in breast-fed children. The reasons for this are explained below. The following cases illustrate well the common history of a sudden onset of napkin irritation immediately after weaning, and the second one also the necessity in severe cases of conscientious attention to the details of the method of treatment advised below.

CASE 577.—C. M., aged 1 year, has been fed entirely at the breast and had been an exemplary infant, until one week before seeking advice. Since weaning the baby a week ago a strong smell of ammonia had been noted, especially from the morning napkins; the child has cried every time he passed urine, and ulcers have appeared on the scrotum and the tip of the prepuce. Boric treatment relieved the dysuria in one day and healed the ulcers in one week.

CASE 581.—C. G., aged 10 weeks, was sent in by a doctor with a request for circumcision on account of severe dysuria accompanied by ammoniacal ulceration of the thigh, scrotum, buttocks, and prepuce. The symptoms had been present since the child was weaned two months before. Boric treatment was advised and a month later the mother returned armed with another letter from the doctor again requesting circumcision as the boric treatment had failed to relieve the condition. On questioning the mother it was found that she was using very thin non-absorbent cloth napkins, and was treating five or six in one cupful of solution. She was told to get towelling napkins and was carefully coached in the proper boric routine. On reporting one week later the lesions were practically healed.

Ætiology and Pathology.

For a proper understanding of the ætiology of ammoniacal napkin dermatitis we are indebted to the observations of Zahorsky [3] and Brenneman,[2] and especially to the experimental researches of Cooke [3 4]

on the subject. It is largely owing to these researches that the condition has been placed upon a firm basis as a clinical entity and its causation clearly demonstrated. Cooke showed that the lesions were produced by ammonia and that the ammonia was liberated from the urea of the urine by the action of an intracellular urease present in a bacillus which inhabits the colon in a large percentage of normal children.

He obtained this organism (*B. ammoniagenes*) in pure culture and studied its peculiarities. It is a Gram-positive, non-motile, aerobic bacillus forming a short, straight rod with well-rounded ends, and measuring from 0·8–1·4 microns in length. Occasionally larger forms are met with, and in older cultures involution forms are common. On culture the colonies as a rule show a faint yellowish pigmentation. The organism is non-pathogenic and does not ferment the ordinary sugars or form spores.

The bacillus flourishes best in a medium which is on the alkaline side of neutrality, while an acid environment causes cessation of growth. Thus, in the highly acid contents of the large intestine of the normal child the organism will not flourish. If the acidity be diminished it will begin to flourish, and will multiply the more actively the nearer the reaction of the contents of the bowel tends towards alkalinity.

Inoculated into a solution of urea or into fresh sterile urine under conditions favourable for its growth, it produces ammonia in considerable quantity in a very short space of time. It is the ammonia produced in this way in the urine-soaked napkin which is responsible for the irritation of the underlying area of skin. This point was conclusively demonstrated by Cooke as follows: He applied a wet dressing of a pure culture of the *B. ammoniagenes* to his own forearm for 12 hours without the development of any lesion. A wet dressing of urea solution again caused no irritation, but a wet dressing of urea solution inoculated with *B. ammoniagenes* produced a strong smell of ammonia and a typical glazed erythema in the course of a few hours.

It is clear from what has been said that alterations in the chemical reaction of the contents of the large intestine are of importance. The normal acid reaction inhibits the growth of the *B. ammoniagenes* sufficiently to prevent a significant production of ammonia in the napkins. If the acidity diminishes, the organisms increase in number and the production of ammonia correspondingly increases. Debre, Goiffon, and Rochefrette [5] have shown that the stools of breast-fed babies are highly acid in reaction, while those of bottle-fed infants become slightly alkaline, approximating in reaction to the fæces of the adult. It is clear, therefore, that the *B. ammoniagenes* can flourish actively in the stools of bottle-fed children, and that, consequently, napkin irritation is more frequently met with among them, whilst it is rarely seen in the purely breast-fed infant.

This observation furnishes the explanation of the fact previously noted, that it is a common experience to elicit a history that ammonia production, dysuria, and dermatitis have first made their appearance within a day or two of weaning the child from the breast. (See Cases 577 and 581 described above.)

"*Ammoniacal Storms.*"

In bottle-fed children and in those past the age for bottle-feeding, it is obvious that the chemical reaction of the stools must vary considerably from time to time according to the diet and a host of other factors, and that therefore the activity of the bacillus will also vary from time to time. As a result, we find that children who suffer from ammonia production do so in recurrent attacks. They are, in fact, liable to what we are in the habit of referring to as "ammoniacal storms," which last for a varying period. Each storm is accompanied by erythema or excoriation of the napkin area, and when the child passes urine through the irritated ring of skin at the tip of the prepuce, pain is caused and the infant screams.

In the already circumcised child, if a storm occurs, the delicate epidermal surface of the tip of the glans penis bears the brunt of the irritation in the absence of its natural and more resistant protector the prepuce, resulting in the development of a meatal ulcer.

The liability of ammonia formation to take place in these storms explains why some children may develop meatal ulcers immediately after circumcision, while in others its appearance is long delayed. No circumcised child is immune from this complication so long as he continues to wear napkins even at night. The largest meatal ulcer which we have met with appeared during an intense ammoniacal storm nearly 18 months after circumcision, when the boy had long given up wearing napkins during the day, but was still wearing them during the night. The two following cases illustrate the intervals which may elapse between circumcision and the development of a meatal ulcer, their lack of response to empirical methods of treatment, and their ready response to the boric acid treatment.

CASE 535.—H. I., aged 8 months, was circumcised on account of dysuria at the age of 7 weeks. He was cured after the operation until two months before being seen, when a meatal ulcer appeared, with very severe dysuria, erythema, and a smell of ammonia. The ulcer has persisted unchanged in spite of the trial of the usual methods of treatment. Boric treatment was advised with the result that the ulcer healed within a week.

CASE 600.—H. H., aged 1 year 6 months, was circumcised shortly after birth as a routine measure. He has suffered from severe dysuria during the last fortnight. The boy wears napkins only at night now, but these are very ammoniacal when removed in the morning. There was a very large meatal ulcer covering half the glans and a mild erythema of the napkin area. Boric treatment of the night napkins relieved the dysuria in 48 hours and healed the ulcer in a week.

The more ammonia there is liberated in the napkins the more alkaline do the contents of the napkin become, and, consequently, the more rapidly does the offending bacillus proliferate. Once ammonia appears, therefore, a vicious circle is initiated, so that ammonia is produced in larger and larger amounts, and this explains Cooke's observation that the intensity of the irritation is influenced by the length of time during which the napkins are allowed to lie in contact with the child in a wet condition. It will be seen later that it is this vicious circle which we aim at breaking by means of the boric method of treatment.

Other subsidiary factors which may influence the condition are the following: (1) the care exercised in keeping the buttocks clean and powdered; (2) boiling the napkins, rather than merely washing or rinsing them; (3) the type of soap used for the child, the cheaper brands of soap being often strongly alkaline in reaction.

It is because of attention to these details that the severe types of irritation are rare amongst better-class children.

Differential Diagnosis.

The three main skin affections which must be mentioned are syphilis, the common intertrigo, and impetigo.

1. *Syphilis.*—It was formerly believed that many persistent napkin rashes were attributable to hereditary syphilis. That the frequency of this association has been exaggerated there can be little question, as most of the so-called syphilitic rashes in the napkin area present the features which we are accustomed to see in ammoniacal irritation, and respond readily to efficient treatment directed towards this condition. Certain cases will be found to be associated with other signs of hereditary syphilis and a positive Wassermann reaction. It is probable that the unhealthy syphilitic child is more than usually liable to show the severer manifestations of ammoniacal dermatitis. The true syphilide is, of course, occasionally encountered, but in it the lesions will be found to lie in the true skin and therefore to be deeper than the epidermal ammoniacal lesions.

2. *Intertrigo* presents quite a different picture from ammoniacal dermatitis, and if a true conception of the ætiology of the latter condition be kept in mind,

no difficulty can arise. The most essential point of difference lies in the fact that the ammoniacal lesion affects the convex surfaces of the skin folds in the napkin region and spares the clefts, while conversely, intertrigo essentially affects the clefts where skin surfaces are in contact and spares the convex surfaces, at any rate, in the milder cases. Intertrigo also presents a typical moist "weeping" surface of a brilliant scarlet colour, which is not seen in the ammoniacal erythema. The history of an ammoniacal odour in the napkins should be absent in intertrigo, but the mixture of serous discharge with the urine and fæcal matter in the napkin of an ill-kept child causes a foul odour which may be mistaken for ammonia. Lastly, intertrigo does not respond to treatment directed towards an ammoniacal lesion.

3. *Impetigo* may be grafted on the surface of an ammoniacal lesion. It shows a crusted appearance which is not seen in the uncomplicated napkin dermatitis, and similar lesions are usually present on the scalp or face.

Treatment.

Having regard to the ætiology of the condition, attempts to treat ammoniacal dermatitis must proceed along one of two lines: (1) dietetic, directed towards increasing the acidity of the contents of the large intestine; or (2) treatment of the napkins directed towards preventing the production of ammonia in them.

It is quite obvious that circumcision cannot influence the irritative process, and exposes the child to the possibility of developing the most distressing of all ammoniacal lesions, the meatal ulcer. In cases requiring circumcision, we either postpone operation till napkins are no longer being worn or else perform the operation after all symptoms of dermatitis have cleared up under appropriate treatment, first warning the mother that the treatment will need to be continued as long as the napkins are worn.

1. *Dietetic Treatment.*—Immunity from ammoniacal dermatitis adds another to the already overwhelming list of advantages of breast-feeding. In the presence of established ammoniacal dermatitis, attempts to alter the reaction of the contents of the large intestine by dietetic methods have been found disappointing by all workers on the subject. Accurate regulation of feeding to reduce imperfect digestion to a minimum is obviously a necessity in those cases complicated by slight degrees of enteritis. Increasing sugars in the diet at the expense of fats is said to render the stools more acid in reaction, but we have found this disappointing in practice, and, in view of the success attending the treatment of the napkins, we have not pursued this line of treatment further.

(2) *Treatment of the Napkins.*—The napkins form the only link at which the chain of events may be broken. When ammonia has actually been formed it is impossible to prevent its action on the skin by the application of the various ointments which have from time to time been suggested. Cooke showed that low concentrations of various antiseptics would prevent the production of ammonia in the test-tube, and, applying this observation to clinical practice, he conceived the idea of impregnating the napkins with antiseptics in order to prevent, or at all events, to delay, the bacterial action at work. The most efficient of these antiseptics is probably mercuric chloride, but undoubtedly the safest and simplest is boric acid, which we have made use of throughout. Cooke prefers the use of 1-4000 mercuric chloride prepared by dissolving a 7½ gr. tablet in two quarts of water. We feel, however, that to issue tablets of mercuric chloride to people of the hospital class, often living under very crowded conditions, is to run an unjustifiable risk of accidental poisoning. Boric impregnation of the napkin has proved extremely valuable in hospital work. The method is cheap, easy to apply, harmless, and very effective. After one experience of its effect in quietening that source of domestic discord, a screaming infant, the mothers themselves become the strongest advocates of the method. Admittedly one finds that certain of the more severe forms of the ulcerative type are a little slow in responding to the treatment on account of the presence of a superadded infection, but even these cases usually clear up in the course of a few weeks. Failure can usually be traced to the fact that the details of the method are being imperfectly carried out. (See Case 581 described above.)

Routine.

We are in the habit of giving to the mother the following printed instructions:—

Instructions for Boric Treatment of Napkins.

Obtain a packet of boric acid crystals. (Prescription given).

Treat all napkins* / Night napkins only } in the following manner.

(* The inapplicable words to be deleted.)

1. All napkins to be boiled thoroughly and then dried.
2. Add a dessertspoonful of boric crystals to a breakfast cupful of boiling water.
3. Soak the dried napkins in this solution, then wring out and hang up to dry. It is usually possible to treat two or three napkins in this way from one cupful.
4. Keep the napkin area of skin clean and dry, and change napkins frequently.

By this procedure the napkins are impregnated with boric acid crystals in a fashion similar to that used in the manufacture of boric lint. It is also of importance that suitable diaper materials should be used. Turkish towelling and Harrington are among the best, as they are fairly absorbent, withstand boiling well, and are of a non-irritating texture. Waterproof knickers should not be worn, as they keep the napkin region moist and also are apt to lead to undue economy in the use of napkins. In dealing with cases of severe dermatitis rigid attention to the details of the method of treatment may make all the difference between success and failure. (See Case 581.)

Treatment of Meatal Ulcers.—Before appreciating the true cause of this complication the treatment adopted was the passage of bougies to stretch the meatus and the application of a bland ointment to prevent the lips of the meatus from becoming gummed together by the exudate. The bougie method of treatment is definitely harmful, since by dilatation it exposes more of the urethral mucous membrane to the action of the ammonia, and, by lacerating the inflamed lips of the meatus it may cause cicatrisation and eventually stricture of the meatus. The boric method of treatment is uniformly successful in these cases, as demonstrated below. (See Cases 535 and 600.)

Results.

Recently we have treated with the boric method a consecutive series of 103 cases of dysuria in children of the napkin age presenting the signs and symptoms of ammoniacal irritation, and our results have been almost uniformly good.

The series has included instances of all types of ammoniacal lesions and may be classified as follows:—

1. Cases of dysuria of very short duration, not presenting any very obvious erythema, but in which an ammoniacal odour from the napkins has been noticed	17
2. Cases presenting a more or less diffuse mild erythema of the napkin area without excoriation or ulceration	23
3. Cases of preputial dermatitis	23
4. Cases presenting excoriations or ulcerative lesions most intense on the buttocks and scrotum	26
5. Cases of meatal ulceration	14

In all classes boric impregnation of the napkins has resulted in rapid cure almost without exception. In Classes 1 and 2 the cure is startlingly rapid, the dysuria being in all cases relieved in from 12 hours to two days. In the excoriated and ulcerated, Classes 3 and 4, a cure takes longer, as one might expect, but all lesions are usually healed in from one to three weeks. Lastly, the cases of meatal ulceration respond extremely well to the boric treatment, as even ulcers which have persisted for months in spite of other methods of treatment heal almost without exception in less than one week.

It is obvious that, if a child is liable to the development of "ammoniacal storms," the boric treatment must be continued after the lesions are cured, as long as the napkins are worn. It is not an uncommon experience to hear that a mother ceased to treat the napkins when the baby was apparently cured, but has hurriedly commenced again when a recurrence of the ammonia and dysuria made itself manifest. The following case illustrates the persistent tendency to relapse and the necessity for continuing boric treatment even in the absence of symptoms.

CASE 570.—J. S., aged 8 months, reported with dysuria and ammoniacal napkins of one month's duration. There was a well-marked preputial dermatitis and some excoriation of the scrotum and thighs. The prepuce was retractable, but constricted the glans considerably, therefore boric treatment was advised, to be followed by circumcision after the irritation was cured. The irritation and dysuria were gone when the child reported in ten days' time, but circumcision was delayed on account of a small perianal abscess which was incised. After the abscess had healed circumcision was arranged for. Before this was carried out the mother reported because severe recurrence of dysuria and dermatitis had taken place. On questioning her she stated that, as all symptoms had gone, she had ceased to treat the napkins, with the result that an immediate relapse took place. Boric treatment again healed the ulcers in about a week, and circumcision was then carried out, the mother promising to continue the treatment as long as napkins were worn.

The average mother will state quite definitely that the treatment does not add noticeably to her domestic duties.

It is worthy of note that, although we have consistently circumcised all children referred to us in whom a true phimosis (as we shall define the term in the next portion of our article) existed, yet the number of circumcisions performed in hospital has been decreased by well over 50 per cent. since the relationship of dysuria to ammoniacal irritation has been recognised and efficiently treated by the boric method.

Summary.

1. The symptom of dysuria is more often produced by chemical irritation than by any preputial narrowing.
2. The chemical irritant at work is ammonia, which is formed in the napkins by the action of a specific organism from the colon. This organism flourishes in an alkaline medium and is capable of splitting up urea with the liberation of ammonia.
3. The signs of ammoniacal irritation are confined to the napkin area and present definite clinical features, some of which are often misinterpreted.
4. The occurrence of meatal ulceration following circumcision is due to the continued action of the ammoniacal irritation after removal of the covering prepuce.
5. A satisfactory method of treatment by impregnation of the napkins with boric acid is described.

PART II.

THE STATUS OF CIRCUMCISION AS A SURGICAL PROCEDURE.

Circumcision lays claim to being the oldest surgical operation. It is first mentioned in the Book of Genesis, when Abraham is circumcised at 99 years of age, as a sign of his covenant with God. Among the Jews it has persisted throughout the ages as a religious rite. The date of its introduction as a surgical procedure is uncertain. It has become, if not the most common, certainly one of the most common surgical operations carried out to-day, and in our opinion one which is carried out far too frequently. We have been asked at one time or another to circumcise children who had no phimosis for such various conditions as prolapse of the rectum, skin diseases, enuresis, hypospadias, tuberculous disease of the kidney, and digestive disorders. In these cases the prepuce was blamed either for producing the symptoms or for being an aggravating factor. It has seemed desirable to make an attempt to define what criteria justify the performance of the operation. Circumcision from the religious standpoint is not considered in this paper.

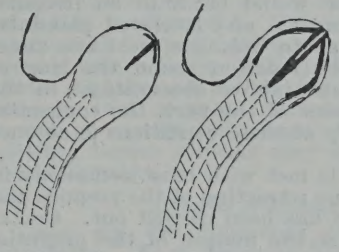
Since a correct conception of the development of the prepuce and glans is necessary to a complete understanding of the origin of phimosis a brief embryological summary becomes necessary.

Development.

Incorrect accounts of the development of the glans and prepuce are found in many text-books. A common error is that the tip of the genital tubercle is said to represent the glans penis alone, while the prepuce is described as a hood of skin growing forward to cover a previously exposed glans.

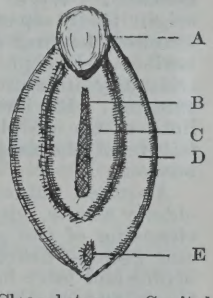
Credit is due to Berry Hart [11] and Wood Jones [10] for giving a full and correct account of the development of this part. With regard to this Wood Jones says: "Some degree of adhesion between the glans and prepuce is normal, and in regarding such adhesions as being the products of inflammation—or as anything other then entirely natural processes of development—an incorrect idea is gained of the condition, and an interesting page of embryology is overlooked." By studying embryos at various stages of development Berry Hart and Wood Jones were able to show independently that the genital tubercle (Fig. 1) is a skin-covered projection from the interior of which the future glans is sculptured out by the invasion of a mass of epithelial cells. The cloacal stage is common to both sexes (Fig. 2) and only later does the

FIG. 1.



The genital tubercle showing stages in formation of the glans and the tunnelling of the glans by the urethra.

FIG. 2.



Cloacal stage. A, Genital tubercle. B, Urethral groove. C and D, Inner and outer genital folds. E, Anal orifice.

sexual differentiation of the external genital organs become apparent. While in the female the inner and outer genital folds become transformed into the labia minora and majora respectively, and the genital tubercle becomes the clitoris, in the male the outer genital folds from the scrotum, and the inner genital folds fuse together over the urethral groove to form the penile urethra, the line of fusion being marked by a raphé on the under surface of penis. Most of the penis is formed by the genital tubercle, the tip of which gives rise to the glans and the prepuce, still undifferentiated from one another at this stage. The urethral groove does not invade the tip of the genital tubercle—i.e., the future glans. That portion of the urethra which traverses the glans is formed in a different fashion. A solid rod of epithelial cells burrows into the glans itself, and becomes canalised by the breaking down of the central cells of the rod. This occurs about the seventh month. At a later date an epithelial cell mass grows into the tip of the genital tubercle and sculptures out the glans from the overlying skin.

The prepuce is eventually separated from the glans by a breaking-down of cells, but this has scarcely begun by the time the urethra has perforated the glans. The future preputial space is filled with epidermal cells which become flatter and flatter and reach a stage comparable with the superficial cells which are shed from the skin surface. The prepuce and glans may not become separated until some weeks after birth. Should this breaking-down be incomplete or delayed it is not difficult to account for the presence of adhesions between the prepuce and glans, nor to see that an adherent prepuce is usually due to delay or arrest in development. True phimosis is most probably due to an error in development.

Ætiology of Phimosis.

Phimosis is defined as a stenosis of the preputial orifice; or, as Bland-Sutton [9] puts it, "the glans is muzzled by its prepuce." The condition may be congenital or acquired, and opinion varies as to which is the more common in childhood. By acquired

phimosis is meant the chronic inflammatory changes which are said to result from the irritation of the preputial sac by stagnating urine, smegma, and so forth. When we commenced this investigation we were inclined to consider the acquired form as being the more common. Since becoming aware of the frequency and importance of ammoniacal irritation and of the rarity of true chronic balanitis, we now believe that the acquired form of phimosis is very rare. After careful examination we have not seen a single case which we could definitely classify as an acquired phimosis, except those which come under two classes, occasionally met with. These are: (1) the case in which stretching has led to splitting of the preputial orifice in several places; the scar tissue resulting from this laceration causes a phimosis, for which circumcision has to be carried out; (2) the case of temporary acquired phimosis, due to œdema—resulting from ammoniacal irritation affecting the tip of the prepuce. Only when the œdema has subsided under treatment will retraction be found possible.

The adhesions which are found between the prepuce and the glans are filmy and soft, although on occasion they may be fairly firm, and they separate cleanly (like lines of cleavage in fascial or intermuscular planes) leaving a smooth, intact, and glistening glans beneath. Were these adhesions inflammatory in origin their separation would occur in an irregular manner, leaving an uneven and lacerated glandular surface. Except in acute balanitis we have never seen any inflammatory reaction round the ring of smegma. Reviewing the above observations in the light of the development of the part, the congenital nature of the majority of these conditions is at once obvious.

Acquired phimosis is met with most commonly in elderly adults, where no retraction of the prepuce and cleansing of the glans has been carried out. Cracks and fissures develop at the margin of the preputial orifice and later become infected and give rise to scar tissue and so phimosis. Preputial stones are apt to form in such circumstances, and these are the cases in which penile cancer is most commonly seen.

Types of Phimosis in Infancy.

In the infant there are three types of prepuce which will not retract: (*a*) true phimosis, (*b*) adherent prepuce (both congenital), and (*c*) temporary acquired phimosis.

(*a*) *True phimosis* is said to be present when, owing to narrowness of the actual orifice of the prepuce, retraction of the prepuce to the coronal sulcus is either impossible or, where possible, causes paraphimosis from constriction of the glans. True phimosis is much less common than it is generally supposed to be. In these cases the correct and, in fact, the only treatment is circumcision, or one of the plastic modifications of this operation.

(*b*) *Adherent prepuce* may be said to exist when it is the presence of adhesions between the glans and the prepuce which prevents retraction. Separation of these adhesions usually permits of fairly easy retraction of the prepuce. This is a very common condition, and one in which circumcision is not needed, as separation of adhesions and retraction relieves the condition.

We examined a consecutive series of over 50 male infants at the Simpson Memorial Maternity Hospital within ten days of birth; in not one of these could the prepuce be retracted without first separating adhesions or stretching. Not more than two of these 50 cases could be called cases of true phimosis.

The differential diagnosis between true phimosis and adherent prepuce, as defined above, is not always so simple as might appear. A definite degree of true phimosis offers no difficulty, for a gentle attempt at retraction of the prepuce usually displays well the typical "miniature proboscis" like end of the prepuce and also demonstrates the unlikelihood of any simple dilatation of the orifice being effective. It is in the lesser degrees of true phimosis where differentiation is not possible by mere inspection. Here all adhesions must first be thoroughly broken down with the aid of a probe, after which the result of an attempt at retraction will make the diagnosis obvious—e.g., an adherent prepuce will now retract fairly easily, and if left retracted for a moment or two does not cause constriction of the glans.

True phimosis and adherent prepuce are symptomless conditions. A true phimosis with sufficient stenosis to cause mechanical obstruction to micturition is, in our experience, a very rare condition.

(*c*) *Temporary acquired phimosis* has already been mentioned and requires no further discussion.

Clinical Features.

In a series of over 600 cases sent up for circumcision, the usual reasons for seeking surgical relief were grouped thus: (1) dysuria, 53 per cent.; (2) symptomless cases in which circumcision has been advised, often for no very obvious reason, by a doctor or nurse, 31 per cent.; (3) paraphimosis, 1·5 per cent.; (4) acute balanitis, 6·5 per cent.; (5) preputial dermatitis, 8 per cent. Uncommon reasons were ballooning of prepuce, hypospadias, and sebaceous cyst.

The indications for circumcision afforded by the above clinical features deserve consideration.

The cases of *dysuria* in Group 1 are almost invariably the result of ammoniacal irritation, as also are those of preputial dermatitis in Group 5 (see Part I.). In the presence of ammoniacal irritation, circumcision is contra-indicated. These two groups contain many cases of adherent prepuce and several cases of true phimosis. The former are treated by separation of the adhesions, retraction and lubrication of the glans with vaseline, while in the latter circumcision is postponed if possible until the child no longer requires napkins. If the circumcision cannot be postponed, it is carried out under the boric régime, and not until the signs of ammoniacal irritation have been cleared up by this treatment.

Symptomless Cases.

The cases in Group 2 were constituted exclusively of true phimosis and adherent prepuce. They were entirely symptomless, and had either been noticed by the family physician or nurse, or by us in the course of the routine examination of cases sent up on account of a hernia or hydrocele.

The cases of *paraphimosis* in Group 3 form only 1·5 per cent. of the total cases. They occur most frequently in children after the third year of life. Reduction can be effected easily in the great majority of cases after steady compression of the glans in a swab for a minute or two. In difficult cases two other methods are helpful; firstly, that advocated by C. W. Cathcart, in which the œdematous and congested glans is wrapped in a broad elastic band and left for 15–20 minutes; or, secondly, multiple punctures of the glandular mucous membrane by the point of a fine needle to relieve congestion and œdema. Thereafter compression of the glans and œdematous collar of mucosa should render reduction of the paraphimosis possible. In our opinion one attack of paraphimosis forms an indication for circumcision as soon as all œdema has settled down and the parts have resumed their normal appearance. If this is not done the condition may be expected to recur sooner or later.

Group 4 comprises the cases of *acute balanitis*, which in our experience is not associated with phimosis. On the contrary, it is most commonly met with in children of 2 years of age or older with a rather long and easily retractable prepuce. The infection is most probably carried to the preputial sac by dirty fingers, and that would explain its high incidence in the easily retractable type of prepuce and its absence in infancy. A true gonococcal infection may occur, but it is not by any means common. If recurrent attacks occur, there can be no objection to the treatment of this condition by circumcision during a quiescent interval, as it is difficult or impossible to improve the personal hygiene of the class of child in which it is met with. As the con-

dition has no relationship to the ammoniacal napkin, circumcision may be carried out without fear of the unpleasant complications, such as meatal ulcer, which may follow the operation in younger children. It is our custom to treat the acute condition by four-hourly fomentations. Irrigation of the preputial sac with weak boric acid solution can be employed should it be deemed necessary. We have not found a dorsal incision of the prepuce necessary in the acute stage.

The rare cases in which *ballooning of the prepuce* is present, and of sebaceous cysts of the prepuce, should be treated by circumcision. Hypospadias of the less severe glandular type, with a hood-shaped prepuce which overhangs the glans, should on no account be treated by circumcision, as the prepuce is a valuable asset to a plastic operation should this be found necessary.

Circumcision: Indications and Contra-indications.

Indications.—The chief indications for circumcision, based on the foregoing considerations, are: (1) true phimosis, (2) paraphimosis, (3) acute recurrent balanitis. As in other operations, the performance of circumcision can be justified only by the prospect of definite benefit to the patient. We believe it is contra-indicated except for the above-mentioned conditions. Certain specific conditions in which it should not be practised may, however, be mentioned.

Contra-indications.—The special contra-indications are as follows: (1) ammoniacal irritation (irritative dysuria, or dermatitis); (2) adherent prepuce (uncomplicated by phimosis); (3) enuresis; (4) the presence of certain local anomalies: (*a*) webbed penis, (*b*) small penis, with large suprapubic pad of fat, (*c*) hypospadias with hooded prepuce.

The relationship of circumcision to (1) ammoniacal irritation, and (2) adherent prepuce have already been considered.

Enuresis.—We do not know of any circumstances under which enuresis may be benefited by circumcision. Indeed, the general consensus of opinion is that the operation tends to make the condition, especially in cases of psychical enuresis, definitely worse.

Local Anomalies, in the Presence of Phimosis.—(*a*) Various degrees of *webbed penis* are met with. Circumcision gives a very bad æsthetic result; therefore, stretching and retraction should be given a good trial first.

(*b*) *Small penis with large suprapubic pad of fat.* This has also been called the "fat boy" type of penis. When circumcision is carried out here the penis is liable to disappear from view in the suprapubic pad of fat, to the great alarm of the parents. Here, again, the æsthetic result of circumcision leaves much to be desired, so that it is advisable to persevere with stretching and retraction, at least until the parts by growth have become more normal.

Preventive Treatment.

Every male child should have its foreskin separated or stretched and retracted in the first fortnight of life. We consider that it should be made part of a maternity nurse's duty, before paying her last visit to the mother and child, to free all adhesions by gently sweeping a probe round between prepuce and glans. Then she should retract the prepuce, clear out smegma, and apply vaseline to the glans. She should be well instructed in the proper method of doing this during her hospital training. The nurse should instruct the mother to retract, cleanse, and lubricate the prepuce and emphasise the importance of doing this each time the child is bathed. If the prepuce is difficult of retraction the medical man in attendance should be consulted as to the advisability of circumcision.

This routine, we feel, would not only tend to prevent the circumcising of cases in which the operation is not really necessary, but would also bring all cases of true phimosis under medical supervision at an early date. It would also be the means of educating the public in what is to them largely an unknown hygienic precaution—the proper care of the preputial sac.

Method of Separation of Adhesions, Retraction, and Stretching of Prepuce.

Separation of adhesions is first carried out on the dorsum of the glans by introducing a sterilised probe under the prepuce. (Some practitioners use the rounded end of a sterilised hairpin.) By means of the probe separation is first carried back to the corona, and then round each side to the frenum on the under-surface. Thereafter the foreskin is retracted until the coronal sulcus with its ring of smegma is completely exposed. The smegma is removed with a moist swab or piece of cotton-wool, the glans is lubricated with vaseline, and the prepuce drawn forward again. It is our experience that some cases, said to have been recently stretched by the doctor or nurse, have only been incompletely separated, as adhesions still persist at the corona and the ring of smegma is still intact.

Where adhesions are slight attempts at retraction of the prepuce may separate all adhesions and thus permit full retraction. When carrying out retraction one should always avoid stretching the region of the frenum too much, as this delicate structure may be easily torn and a brisk hæmorrhage result. The glans, by virtue of its shape, is a very suitable dilator for the prepuce.

Where the orifice of the prepuce is narrow it may require stretching before separation of adhesions or retraction is attempted. This is most easily done by inserting the closed blades of a pair of sinus or fine-pointed artery forceps within the orifice, opening the blades slightly and withdrawing them open. This is done in two or more diameters. The manœuvre should be carried out aseptically and gently, for if splitting occurs stenosis may result later from scar tissue formation.

Methods of Circumcision.

These are too numerous to describe or even enumerate. Each operator has his own particular method and finds it satisfactory. There are, however, one or two points in technique that should be noted.

To gauge the correct amount of foreskin which requires amputation may be difficult at first. The beginner usually removes too little, the possibility of damage to the glans being always in his mind. In estimating the amount to remove the position of the coronal sulcus should be defined by palpation. Immediately in front of this a pair of forceps—e.g., Kocher's pressure forceps—is applied across the prepuce. The forceps is applied obliquely downwards and forwards to avoid damage to the frenum. As the forceps is gradually tightened the prepuce is drawn forwards until the forceps has cleared the glans. Then with a knife the prepuce is divided immediately proximal to the forceps. Damage to the glans is avoided by maintaining traction on the forceps while the section is being made.

After removal of this major portion of the prepuce the remaining cuff of its internal layer is slit up in the middle line with scissors almost to the corona. The two flaps thus formed are turned back. No further paring of the internal layer should be done as the final result is better when 5 to 10 mm. of it is left. Paring the inner layer close to the corona is to be depreciated. The stitches used should be interrupted and tied rather loosely, as tight or continuous stitches may cause undue constriction, necrosis, and œdema. As the mattress stitch often advocated at the frenum is apt to give rise to an area of necrosis we prefer to use a simple stitch on each side of the frenum. It is true that stitching is not essential. A strip of gauze can be wrapped round the corona, coapting the internal and external layers of the foreskin. This is surrounded and fixed by a narrow strip of tape. If the two ends of this latter are twisted together gentle pressure is maintained along the line of suture. This method we first saw employed by a Rabbi, who used neither artery forceps, ligatures, nor stitches.

Routine Circumcision: Arguments for and against.

The medical profession is rather sharply divided on this subject. There are the extremists who advocate circumcision for one and all, irrespective of the absence or presence of any local pathology. Others only resort to circumcision in the cases that really require it on pathological grounds.

The principal arguments that the extremists put forward in favour of routine circumcision are three in number: (1) in the interests of hygiene; (2) to reduce

the risk of contracting venereal disease; (3) to reduce the risk of epithelioma of the penis.

(1) The operation of circumcision has been urged in the interest of hygiene and cleanliness. We feel that to advise any otherwise unnecessary operation, however small, merely as a labour-saving expedient is contrary to the ethics and principles of the healing art. The remedy lies for the main part in the education of the mothers through the medium of the maternity nurse.

(2) There is a widespread belief that venereal disease, especially gonorrhœa, is less frequent among the circumcised than among the uncircumcised. It is therefore thought that its incidence among Jews is considerably less than among the rest of the population. It is the impression of practitioners who work among Jews that the incidence of venereal disease does not differ materially in that race from its incidence among the uncircumcised. With regard to this, Dr. Fishberg,[12] of New York, states: "It appears that even circumcision, which was considered one of the reasons for the immunity of Jews to venereal diseases, is not of material avail when they expose themselves to the dangers of infection."

(3) It is probably a fact that epithelioma of the penis affects exclusively men who have suffered from a life-long phimosis. We fail, however, to see why this should be used as an argument in favour of the circumcision of children who are not the subjects of phimosis.

The chief arguments against routine circumcision are: (1) anæsthetic risks; (2) certain possible complications—e.g., cellulitis, meatal ulcer, strangulation of glans by a hair.

(1) An anæsthetic is often dispensed with when circumcision is carried out in the first month of life. Circumcision later in childhood requires the administration of a general anæsthetic. Anæsthetists who have much experience of children's work admit that they are specially watchful during the administration of an anæsthetic for a circumcision. As might be expected in an operation conducted on the genital organs, a considerable reflex fall of blood pressure occurs on clamping or cutting across the prepuce. We have the impression that anæsthetic "scares" are more frequent during the course of a given number of circumcisions than during a similar number of such operations as that for the radical cure of inguinal hernia. It is probable that the anæsthetic mortality is higher also.

In a certain proportion of cases respiratory complications (broncho-pneumonia, bronchitis, &c.) inevitably occur whenever a general anæsthetic is administered, no matter for what operation. In spite of a preliminary routine examination of the chest the percentage of respiratory complications in out-patients, as the majority of these circumcision cases are, must be appreciably higher than in in-patients.

(2) Certain complications are liable to follow circumcision and must therefore be kept in mind. *Meatal ulcer* follows in a certain proportion of circumcisions carried out in the presence of ammoniacal irritation. Serious *sepsis* is admittedly rare, but we know of cases of cellulitis following circumcision which have proved fatal. *Persistent hæmorrhage* may be the first sign of hæmophilia or purpura. A rarer complication is *strangulation of the glans penis by a hair.* This we mention because its occurrence is known to comparatively few. We have seen three cases during the last year. A long hair, probably derived from the child's mother, becomes wound round the coronal sulcus of a circumcised child and gradually cuts into the penis, causing œdema of the glans and an appearance at a first glance similar to a paraphimosis. It will be readily appreciated that the condition is not likely to occur in the uncircumcised child. The presence of œdema of the glans in a circumcised child should lead one to suspect the condition. On opening up the coronal sulcus a little sticky secretion will be found occupying a deep cleft at the bottom of which the offending hair will be found. We have seen an unrecognised case where the hair had completely divided the urethra, producing a very troublesome fistula, and had indeed nearly amputated the glans.

Conclusions.

(1) Adherent prepuce is extremely common, and may be considered normal in the first week or two of life.

(2) True phimosis is not so common as is generally supposed.

(3) Circumcision is carried out too frequently. In many cases separation of adhesions is all that is required.

(4) The chief indications for circumcision are true phimosis, paraphimosis, and acute recurrent balanitis.

(5) The routine circumcision in every case advocated by some is to be deprecated and is not without risks.

We wish to express our gratitude to Miss G. Herzfeld and Mr. Norman Dott, surgeons to the Royal Hospital for Sick Children, for the interest they have shown in these investigations, and to the latter for suggesting the need of the inquiry into the subject. We have to thank Miss Innes, sister in the surgical out-patient department, for much willing help and coöperation. The microscopical investigation of prepuces was carried out in the Experimental Surgery Department of Edinburgh University.

THE CARRIER OF VIRULENT DIPHTHERIA BACILLI.

SOME RESULTS OF TREATMENT BY TONSILLECTOMY.

BY E. H. R. HARRIES, M.D. LOND., D.P.H. LIVERP.,
MEDICAL SUPERINTENDENT, BIRMINGHAM CITY HOSPITALS;

W. M. MACFARLANE, M.B., CH.B. GLASG.,
SENIOR ASSISTANT MEDICAL OFFICER;

AND

F. BRAYSHAW GILHESPY, M.R.C.S. ENG., D.L.O.,
AURAL SURGEON.

UNTIL the active immunisation of non-immunes is adopted in England upon an adequate scale, the persistent carrier of virulent diphtheria bacilli must remain a source of danger to the susceptible child population amongst whom he lives. Hence it is still important to consider the available methods of treating the carrier state.

For the detection of the diphtheria carrier the routine morphological diagnosis of a culture from the swab is quite insufficient. The morphological diphtheria bacilli detected must be put to the proof of a virulence test.

Every year many hundreds of people—adults and children—who are so unfortunate as to harbour harmless diphtheroids, are hurried into infectious diseases hospitals upon the strength of a morphological diagnosis of a culture from the swab, to the needless anxiety of relations and at considerable cost to the community.

For example, in a recent consecutive series of 198 cases admitted to Little Bromwich Hospital, the practitioner before notifying the case had swabbed the throat or nose and received a positive report. 102 of the total showed evidence of clinical diphtheria. The remaining 96 showed no evidence. These latter were reswabbed by the medical officers immediately after admission, and the swabs sent for a report as to the virulence of the organisms present. In 61 of the 96 cases a report was received that the organisms present gave a negative guinea-pig Schick test; in 24 no organisms were found; in 11 only were organisms present which gave a positive guinea-pig Schick test (throat and nose, 2; throat, 5; nose, 4).

The original swabs taken by the practitioner, with possibly one or two exceptions, and all the swabs taken after admission by the medical officers in these cases, were examined in the Birmingham City Bacteriological Laboratory. Dr. H. Henry, the director, also carried out for us all the virulence tests detailed below, employing the guinea-pig Schick test.

The Chronic Carrier.

The chronic carrier of virulent organisms falls into one of two classes. He has either been the subject of a known attack of clinical diphtheria, in which case he is likely to have come under treatment and to be thereafter for a time more or less suspect; or he has never had any recognisable attack, but is discovered, as the result of swabbing contacts, to be harbouring diphtheria bacilli which can be shown to be virulent. He was probably the source of infection.

The chronic carrier of virulent organisms in the throat, whether "convalescent" or "healthy," is always immune—his Schick test is always negative.

In the majority of cases convalescent from diphtheria bacteriological clearance may be stated to be obtained as a general rule by or before the time that the patient is physically fit for discharge.

Hartley and Martin [3] showed that in a group of military cases the rate of clearance might be expressed by a logarithmic curve. Thomson, Mann, and McCartney,[4] in a preliminary study, decided that a patient should be classed as a carrier when the bacilli had persisted for 12 weeks. They state that of a total of 928 cases investigated, diphtheria bacilli persisted in 81 cases after 12 weeks had elapsed, whereas they ceased to be found by that time in 847. The investigation showed the much greater tendency for the bacilli to persist when they infect the throat and nose or the nose only.

The purely nasal chronic carrier of diphtheria bacilli is not always immune. A purely nasal infection tends to produce immunity very slowly; but at any time before this has come about the nasal carrier may become the subject of true clinical nasal diphtheria, and, as a result of his clinical attack, will become an immune "convalescent" carrier. With a few nasal exceptions, however, it is true to say that the chronic carrier of diphtheria bacilli is always himself immune to the disease, either as a result of a frank clinical attack or as a result of immunisation by small repeated infections.

Theoretically from the case of true clinical diphtheria virulent organisms should be recoverable from the infected site in every case.

In a careful study of a long series of cases certified as suffering from diphtheria, and admitted to the South-Western Hospital, Caiger and O'Brien [1] found that "the laboratory worker's diagnosis (i.e., the recovery of virulent diphtheria bacilli) agreed with the clinical diagnosis of the hospital's medical officers in 97·5 of instances." Eagleton and Baxter [2] found that cultures from a case of diphtheria were virulent in 100 per cent. of those examined: from convalescents in 90·9 per cent.; from carriers in only 38·8 per cent. They found "no evidence that virulent cultures if isolated in a pure condition became avirulent."

For the purposes of this paper a carrier may be defined as a patient whose discharge from hospital is being delayed not upon grounds of physical unfitness, but by reason of the fact that he continues to harbour at one site or another *virulent* diphtheria bacilli. We agree that such cases form a small percentage only of the total admissions for genuine clinical diphtheria. The series of 90 cases which we analyse below occurred in an aggregate of 1538 admissions of cases of genuine clinical diphtheria; 81 were convalescent carriers and 9 were cases which on admission showed no clinical evidence of the disease, but which were Schick negative carriers of organisms of proved virulence. None of these nine is known to us to have had a previous clinical attack of diphtheria, but at least two of them are known to have been in close contact with cases which developed severe toxic types of the disease. All these 90 cases had either enlarged or unhealthy tonsils or adenoids, or both.

Futility of Local Antiseptics.

For a long time we restricted our efforts at clearance of the chronic carrier to local application of antiseptic sprays, &c., bacteriological aniline dyes, and diphtheria

vaccines. In a previous paper [5] one of us stated that in his experience the chronic carrier of diphtheria bacilli was almost always the subject of some nasopharyngeal abnormality; that the extensive trials of various methods of clearance carried out by Dr. Olga Payne showed that none of these were reliable; that surgical measures offered much better hopes of success, but

TABLE II.—*Bacteriological Reports Immediately Prior to Operation.*

that in the opinion of the writer, an opinion which as the result of further experience he no longer holds, such operations were preferably not done in fever hospitals.

To show the futility of local antiseptic treatment, or the policy of waiting for the organisms to disappear from unhealthy nasopharyngeal tissues, we have set out the swab records of four of the first batch of cases upon which it was decided to operate. (These are not

included in the later and longer series.) Before operation was resorted to in each of these four cases they had been treated with various local applications, the principal effect of which was to irritate the mucosa (Table I.).

Results of Operative Procedures.

As the results of the first batch of cases which were operated upon in 1925 were so good, it was decided in 1926 to extend operative procedures considerably. The 90 cases detailed below show the results of this extended surgical work. As already mentioned, all were carriers of organisms of proved virulence; 81 were convalescent after a definite clinical attack of diphtheria, and 9 were Schick-negative carriers. Table II. shows the age-groups of the patients and the sites from which virulent organisms were recovered immediately prior to operation.

It will be noted that no purely nasal carrier occurred in the last three age-groups.

In 75 cases tonsils and adenoids were removed; in seven cases tonsils only, and in eight the adenoids only—all, of course, under general anæsthesia. It should be emphasised that the tonsil need not necessarily be enlarged; indeed, of the two it is the small buried tonsil which is more to be feared as a site of continued infection than the hypertrophied one. Such small buried tonsils require to be removed by dissection. In six cases in our series the tonsils were dissected. All cases after operation should wherever possible be returned not to the infected ward from which they came, but to a clean ward set specially apart for such cases. In all our cases when administratively possible this procedure has been carried out.

Av. = Avirulent organisms.

Table III. shows the results of the first bacteriological report after operation.

In Table IV. are shown the days after operation on which the first swabbing was done. It will be noted that ten of the total number were first swabbed in the first six days after operation, and that all of these save one were returned as negative. It is not advisable, as a general rule, to attempt to swab until the seventh day after operation, as the tonsil beds are not sufficiently firmly healed before this time. Hæmorrhage may result from disturbing them with a swab.

It will be seen that in all save 14 cases a negative bacteriological report was received from both throat and nose as a result of the first swabbing after operation.

The 14 cases in Table IV., which on a first swabbing after operation were reported to be still positive, are further analysed in Table V.

It will be noted that the nose failed to clear on the first swabbing after operation in 10 of the 14 cases. In one case in which before operation the nose only was returned as carrying virulent organisms, a primary positive (virulent) swab was obtained from both nose and throat after operation. In one other

case before operation the throat was returned as carrying virulent organisms and the nose avirulent. After operation the throat swab was returned as avirulent and the nose as virulent. It is possible that an error in labelling might account for this discrepancy. All these cases cleared by the periods after operation stated in the table. It will be noted that in no less than five, later tests for virulence from cases which had originally carried virulent organisms were returned as avirulent.

As to whether the organisms had lost virulence or whether the virulent organisms had died out, leaving only avirulent commensals, we express no opinion.

The average time taken for clearance after operation may be summarised as follows. In 58 cases bacteriological clearance—i.e., negative swabs from nose and throat on first and succeeding swabbing—were obtained in an average period of 17·8 days after operation. In 22 of these cases two or more sets of negative swabs were obtained, and in 36 cases one negative set only. In 18 further cases negative swabs were obtained on first and succeeding swabbing, but owing to intercurrent conditions—e.g., measles—discharge from hospital was delayed. Had discharge from hospital been desirable when the swabs were first known to be negative, the average length of time taken for clearance in these 18 cases was 18·8 days after operation. In 14 cases (detailed above) the first swab after operation was positive (T. and N. 3, T. 1, N. 10). Clearance was ultimately obtained in an average of 31·2 days after operation.

In the earlier cases of the series we always waited for at least two consecutive negative sets of swabs from nose and throat after operation before discharging from hospital. But we found that in no instance where the first set of swabs after operation was returned as negative did we obtain a subsequent positive result from either nose or throat. We therefore now discharge from hospital if the primary set of swabs after operation are returned as negative.

By the kindness of Sir John Robertson, medical officer of health of Birmingham, we have been able to collate all the cases detailed in the above series with a list of known "return" cases from the 1926 admissions to hospital. Only 1 of these 90 cases is alleged to have been responsible for a return case; but since the boy's father, who also suffered from diphtheria, was nursed throughout at home, the responsibility of our case is at least doubtful. This boy was discharged from hospital with two consecutive sets of negative swabs and returned to us 20 days later with a positive nasal swab which proved to be virulent. His mother came into hospital notified as diphtheria. On admission she presented no clinical evidence, and her swabs were negative, but as she had received antitoxin before admission, we cannot express a definite opinion.

Potential Carriers.

In the course of the year, in addition to the series of 90 cases of known carriers detailed above 20 further cases were operated upon, not because they were known carriers, but because owing to the unhealthy condition of the nasopharynx they were regarded as potential infecting cases in spite of the fact that in many of them negative swabs had been obtained before operation was advised.

It is significant that one of these cases taken out against advice whilst he still had a moist nose was responsible for a "return" case of diphtheria.

We have not included these 20 cases in our main series for the reason that they were only regarded as potential carriers. In three of the series primary positive swabs were returned after operation—two from the nose and one from the throat.

Conclusions.

It is generally agreed that local antiseptic or bactericidal applications for the purposes of clearing the diphtheria carrier are virtually useless; diphtheria vaccines in our hands showed no results of value.

Tonsillectomy and the removal of adenoids are procedures of much greater value. Thomson, Mann, and McCartney [6] are of opinion "that the operative treatment of the carrier is encouraging, but limited in value" and "that no satisfactory method of treatment has yet been devised to deal with carriers of bacilli in the throat and nose, or nose only, except in cases where the tonsils continually infect the nasal passages and these seem unusual." Operative treatment for the clearance of the carrier is, of course, no new thing.

Friedberg,[7] Ruh Miller and Perkins,[8] Rabinoff,[9] Keefer Friedberg and Aronson [10] (91·3 per cent. negative within two weeks after tonsillectomy), and Weaver [11] (average time of clearance within 18 days after removal of tonsils and adenoids), have all published series of cases. Pilot [12] states that "the tonsils are the foci which usually harbour diphtheria bacilli in carriers and their removal frequently terminates the carrier state."

Tonsillectomy is not an ideal method, but it is a rational and successful one. Although we have never experienced difficulty in obtaining permission for the performance of the operation under a general anæsthetic, there is this possible objection, together with the other drawbacks of a cutting operation under a general anæsthetic.

Kahn [13] has had very successful results with X rays, and Stewart [14] claims good results from treatment with ultra-violet rays, applied locally. We have so far had no experience of either of these methods.

But, after all, the best way to render the immune carrier of virulent organisms innocuous is to secure that he lives not amongst susceptible children, but amongst children who have also been rendered immune by the safe and certain means provided by toxin-antitoxin.

OBSERVATIONS ON THE TREATMENT OF DIABETES BY SYNTHALIN.*

BY E. G. B. CALVERT, M.D. BELF., M.R.C.P. LOND.,

PHYSICIAN TO THE ROYAL NORTHERN HOSPITAL AND LONDON TEMPERANCE HOSPITAL; LATE ASSISTANT TO DIRECTOR OF MEDICAL UNIT, ST. MARY'S HOSPITAL.

FOLLOWING up the discovery by Watanabe and others that the guanidine intoxication of tetany parathyreopriva (Paton and Findlay) was accompanied by hypoglycæmia, Frank, Nothmann, and Wagner [1] investigated the influence of various guanidine derivatives on carbohydrate metabolism in order to find that which would produce the greatest lowering of the blood-sugar and at the same time little or no toxic effects. They started by testing agmatin, the guanidine compound found by Kossel in herring-sperm and later made synthetically. It is amino-buthylenguanidin. By introducing another methyl group a more effective substance, aminopenthylen-guanidin, was obtained, and this in turn was improved upon by lengthening the CH_2-chain, giving us the compound now known as synthalin. In their papers Frank and his collaborators give numerous examples

* This communication was received by us after the publication in THE LANCET of Sept. 3rd (pp. 517 and 509) of the preliminary reports to the Medical Research Council on synthalin, and of our comment thereon.

[1] Frank, Nothmann, Wagner: Klin. Woch., November, 1926, 2100–2107.

of the influence on the blood-sugar of rabbits and dogs of synthalin given subcutaneously and orally, e.g. :—

In a normal rabbit 3 mg. per kilo (*subcutaneously*) lowered the blood-sugar as follows: before administration, 0·131 per cent.; 1½ hours after, 0·124 per cent.; 6 hours after, 0·115 per cent.; 9½ hours after, 0·057 per cent. Convulsions occurred; recovery by giving glucose; living next day.

Dog (pancreas totally removed): 10 mg. per kilo, *subcutaneously*. Blood-sugar lowered from 0·426 per cent. to 0·090 per cent. in eight hours. Recovery from convulsions by giving glucose.

Dog (pancreas totally removed): 20 mg. per kilo *per os*. Blood-sugar lowered from 0·314 per cent. to 0·274 per cent. in eight hours. Another dog similarly treated: 0·318 per cent. to 0·070 per cent. in 14 hours. Recovery from convulsions with glucose.

They point out that in comparison with insulin the action, although slower, lasts considerably longer. The guanidine compounds anchor themselves for a long time to their substrate and are therefore very liable to act cumulatively. Those animals with marked convulsions and other severe toxic symptoms usually respond to glucose administration, but not infrequently die next day.

I shall not allude further to the other animal experiments recorded beyond saying that certain proof is brought forward to indicate that, in a general way, synthalin, like insulin, favours both the utilisation of sugar in the system and its storage as glycogen. Doubtless before long those in this and other countries who are in a position to test the validity of the assertions made as to the effect of synthalin on experimental animals will publish their results.

Effect of Synthalin on the Carbohydrate Metabolism of Diabetic Patients.

My first tests with synthalin were carried out on two severe cases of diabetes on Feb. 27th, 1927. Both patients (females, aged 23 and 25) have received synthalin continuously ever since, and during these six months have been tested regularly once or twice

(Details of dosage given later.)

weekly, and daily at times, particularly at first. As supplies of synthalin increased other cases were added, until in all 13 have received treatment for periods varying from 1 to 28 weeks. In addition, tests have been performed on two normal persons. Six of the patients were treated at the Royal Northern Hospital, one at the London Temperance Hospital, and four in the laboratories of the medical unit at St. Mary's Hospital. The remaining two were private patients—moderately severe cases—who refused insulin injections.

In trying synthalin my aim was to decide the following points: (*a*) Does synthalin lead to increased storage of sugar? (*b*) Does it increase the burning of sugar and so lessen the production of acetone bodies? (*c*) In the event (or non-event) of toxic symptoms is there any evidence of damage to the liver or kidneys?

For (*a*) blood and urine analyses were employed; for (*b*) Rothera's test and R.Q. determinations; for (*c*) the clinical signs, tests for urobilinuria and albuminuria, and the hæmoclasic crisis test in two instances. Van den Bergh reactions were not done.

Group (*c*) can be dismissed in a few words. Although it was felt that the liver was probably slightly poisoned in the toxic cases (gastro-intestinal irritation and general malaise), no positive results were obtained with the tests and no trace of jaundice or tenderness over the liver noticed. Only two cases (4 and 5 in table) showed albumin in the urine, and these had no toxic symptoms. Curiously enough the albumin appeared in both instances only after the drug had been stopped for a few days, and when the blood-sugar had risen to a rather high level again. No explanation is offered.

CASES 1 and 2.—G. B. and G. E. have been investigated together throughout. Both had been under my care for insulin treatment for about three years previous to synthalin. During this time the insulin dosage had been very considerably reduced until a balance between diet and dosage had become more or less fixed for the past year. Case 1 required 22+18 units daily for a diet of 35 g. carbohydrates + 90 g. proteins + 114 g. fat, while G. E. required 25+22 units for a diet of 38 C. + 95 P. + 120 F.

EXPT. 1 (Feb. 27th, 1927).—Both patients: no breakfast and no insulin. Both given 50 mg. synthalin fasting.

Blood-sugar values.	G. B.	G. E.
	per cent.	per cent.
Before synthalin	0·176	0·159
35 minutes after	0·201	0·173
80 „	0·173	0·181
180 „	0·156	0·150
240 „	0·128	0·139
360 „	0·116	0·132

The blood-sugar is lowered in spite of the initial tendency to rise.

EXPT. 2.—A somewhat similar test was done on G. B. on June 26th, 1927, but at the same time respiratory quotient estimations were made. To ensure that the blood-sugar should be up no insulin or synthalin was used that morning, but 20 g. C. were ingested at 8.30 A.M.; 60 mg. synthalin taken at 10.30 A.M.

B.S. at 10.30 A.M. .. .. 0·258%. R.Q. = 0·84.
„ 1.30 P.M. .. .. 0·224%. R.Q. = 0·80.
„ 4.45 P.M. .. .. 0·186%. R.Q. = 0·95.

Experiment repeated four days later, but no synthalin :—

B.S. at 10.30 .. .. .. 0·237. R.Q. = 0·86.
„ 1.30 .. .. .. 0·240.
„ 4.45 .. .. .. 0·221. R.Q. = 0·86.

Urine before the meals contained a small quantity of acetone, but no sugar. The urine collected over the synthalin test contained 4 per cent. sugar and more than double the amount of acetone in the early morning specimen. The acetone did not appear to be increased when no synthalin given. This is strange, as in the cases about to be described acetone tends to disappear under the treatment, though in my experience much more slowly than the German workers affirm. Perhaps the large dose had a toxic effect on the liver not accustomed to the preparation. The result makes it difficult to say anything about the burning of sugar; it seems to offset the indication of the R.Q.'s that such is happening. The experiments point to the fact that synthalin causes sugar to be stored. The gradual disappearance of acetone bodies shown to occur in subsequent tests indicates that synthalin must also cause it to be burnt.

EXPT. 3.—Effect of synthalin on two normal persons (August 17th, 1927):—

—	Male, 69 years.	Male, 21 years.
Fasting blood-sugar	0·108	0·098
70 mg. synthalin given.		
2 hours after	0·112	0·098
4 „	0·118	0·092
6½ „	0·106	0·074

No symptoms except those of ordinary fasting. In the first case there seems to be a slight interference with storage, in the second a definite hypoglycæmia at 6½ hours.

Now to return to the treatment of Cases 1 and 2 with synthalin. The patients were kept strictly to the dietaries on which they were balanced by the insulin already mentioned—i.e., normal blood-sugars at 3–4 hours after "insulin" meals. Synthalin was then used to replace some of the insulin without disturbing the blood-sugar values at the "3–4 hour" periods, the insulin being withdrawn as the blood-sugar fell. The preparation was given continuously in cycles of four days: first day, 25+10 mg.; second day, 25 mg.; third day, 25+10 mg.; fourth day, none. In this way G. B.'s insulin was reduced from 22+18 to 10+6 units daily, and G. E.'s from 25+22 to 10+10 in three weeks. In order to lower the insulin still further an additional 10 mg. synthalin was allowed every fourth day. The blood-sugars remained practically steady for the following week and then almost simultaneously both patients complained of loss of appetite, feelings of nausea, lassitude, and slight headache, but no irregularity of the bowels. The "3–4 hour" blood-sugars had risen to 0·135 and 0·140 respectively, when one might have expected them to be subnormal. The synthalin was stopped for a few days and the insulin increased. Treatment was then resumed with smaller doses and gradually worked up until the original amounts of synthalin and insulin were being given again. G. E. was sick once after this, but G. B. not at all. Omission of the drug for four days cleared up the trouble, and she has been all right ever since. The evening doses of insulin were steadily decreased so long as the blood-sugars 3–4 hours after the morning doses remained normal, and for the past two months both have been taking only 10 units every morning and none in the evening. Moreover, just a week ago G. E.'s blood-sugar had fallen to 0·080 per cent. So she was brought down to 8 units once daily. They are both feeling and looking well, weight maintained, and both working eight hours daily. At present they are having 10 mg. synthalin every evening and 25 mg. every other morning in addition to the insulin. In these two and several other cases the acetonuria was very resistant to treatment, and indeed showed an appreciable, if not considerable, increase for a time. In the end it practically disappeared.

CASE 3 (aged 59). Has been on insulin treatment for almost two years. In the latter part of last year she had through neglect allowed incipient gangrene of the toes to develop. Although she made a good recovery when adequate insulin was given, she remained as a borderland gangrene. She was readmitted for synthalin treatment on July 20th, 1927. Previous to admission she was taking 25+25 units daily. The diet was rearranged and only 15+15 units given so that the blood-sugar would rise. She became stabilised, so that on August 7th, 1927, there was 1 per cent. urinary sugar, a moderate amount of acetone, and a blood-sugar of 0·230. The latter and subsequent blood-sugars were taken four hours after the morning insulin. Beginning on the 8th (i.e., the next day) 25 mg. synthalin were given every morning and 10 mg. every other evening. On the 9th the blood-sugar was 0·206, the 12th 0·190, 15th 0·190, 17th 0·218, 23rd 0·187, 27th 0·168, and the 30th 0·140 per cent. The sugar in the urine and most of the acetone gradually cleared up. She thinks she felt rather better on insulin alone, but is not quite sure.

CASE 4 (63 years), mild, admitted to hospital on June 10th, 1927. Before admission passed about 1 per cent. sugar on 100 g. C. Since admission she has been taking 0 C.+95 P.+120 F., and the urine has been normal. Blood-sugar four hours after food on 14th=0·280 per cent.—high renal threshold. The blood-sugar gradually settled to a fixed figure. Thus on the 28th it was 0·195, and on July 6th and 10th it was 0·210 per cent. Synthalin, 25 mg. every morning and 10 mg. every other night, was begun on the 11th. On 19th the blood-sugar was 0·160, on 26th 0·135, and on August 3rd it was 0·090 per cent. A week after stopping all synthalin the blood-sugar had risen higher than ever—0·283 per cent. Fifteen units of insulin given to this patient fasting, before the synthalin was started, lowered the blood-sugar from 0·160 to 0·098 per cent. in 2½ hours—a very much more rapid action.

CASE 5 (59 years), moderate severity, admitted to hospital on June 7th, 1927, and was given a diet containing 30 g. C. Seven days later the blood-sugar (four hours after food) was 0·330. After another 14 days it was still stable at 0·300 per cent. Next day (29th) synthalin was begun—25 mg. every morning and 10 mg. every other evening. On July 1st the blood-sugar was 0·280, on 19th 0·220, on 26th 0·153, and on August 3rd it was down to 0·115 per cent. The 1½ per cent. sugar in the urine and the small amount of acetone present at the beginning slowly cleared up during treatment. Seven days after withdrawing all the synthalin the blood-sugar had risen to 0·235 per cent.

CASES 6, 9, 10, 11.—Only No. 9 was having insulin (25+20 daily). 9, 10, and 11 developed nausea and general malaise in about one week each on 25+25 mg. daily and without any noticeable influence on carbohydrate metabolism, so the treatments were abandoned as unsuitable. In No. 6 the results were equally disappointing, but the toxic symptoms were longer in developing.

CASE 12.—An out-patient; intermittent sickness and consequent inability to keep to the diet make the results valueless. She had had the drug on and off for nearly five weeks.

CASES 8 and 13.—No toxic effects after 35 mg. daily, and little, if any, influence on the blood and urinary sugar. In 13 the diet was under suspicion, so details will be omitted.

CASE 7 (62 years), moderate severity. The blood-sugar 2½ hours after a breakfast containing 25 g. C. on June 1st, 1927, was 0·374 per cent.; sugar in urine, 6·5 per cent.; no acetone. With slight restriction of the diet the blood-sugar 2½ hours after breakfast on the 10th was 0·276 per cent.—stabilised. On the same day she began a four-day cycle of 35+35+35+0 mg. synthalin. By the 30th the blood-sugar was down to 0·164, and ten days later to 0·147 per cent. Slight loss of appetite caused the dosage to be reduced to 25+35+25+0. The patient was soon all right again and the blood-sugars varied from 0·140 to 0·150 during the next four weeks; no further cumulative effects. The sugar in the urine had disappeared 3½ weeks after treatment was begun; no acetone found at any time.

Summary.

Synthalin has an action like insulin in so far as it appears to cause sugar to be stored and to be used. The German workers offer proof of this in animal experiments and clinical investigations seem to support it. Confirmation of the former is awaited with interest. Although it resembles insulin it acts very much more slowly and is not nearly so consistent—large doses sometimes producing no appreciable effect and comparatively small ones occasionally giving rise to marked toxic symptoms, which, however, soon disappear on withholding the drug. The great advantage of the treatment is that it is taken by the mouth. Table I. shows my results. Out of 13 cases tested, five seem to have done well so far, one fairly well, two uninfluenced, and five were unable to take an adequate amount of the drug without developing symptoms of poisoning. It is the occurrence of the latter that makes one hesitate just yet to pronounce the *apparently* good results as *really* good, fearing lest the lowering of the blood-sugar, &c., might be due, for example, to a slow, insidious poisoning of the liver cells, interfering in some way with the production of new sugar. Up to the present those of my cases that have done well lend no support to such hypothesis, but they do encourage a further and fuller investigation of the preparation.

In conclusion, I want to thank Dr. P. O. Ellison and Dr. H. H. Sanguinetti for valuable help with some of the cases, and Prof. F. Langmead for allowing me to make use of two of his patients. I am also very much indebted to Mr. W. H. McCallum, of Messrs. Allen and Hanburys, and medical friends on the Continent for so kindly assisting me to obtain the synthalin in sufficient quantities.

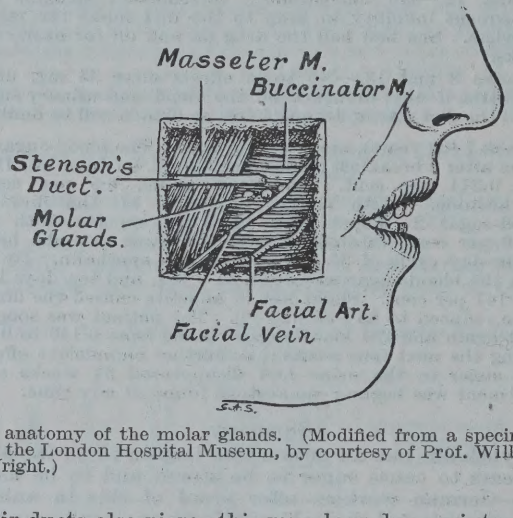
MIXED TUMOURS OF THE MOLAR GLANDS.

BY LIONEL R. FIFIELD, F.R.C.S.ENG.,
SURGICAL FIRST ASSISTANT AND REGISTRAR, AND DEMONSTRATOR OF ANATOMY, LONDON HOSPITAL.

THE purpose of this contribution is not to deal exhaustively with the subject of mixed tumours. It is to draw attention to tumours of this nature arising in the cheek in connexion with the molar glands. In Choyce's "System of Surgery" the question of mixed tumours is summarised thus: "This group of tumours is most commonly represented by the well-known 'parotid tumour,' but others of essentially the same nature are met with in the submaxillary region, lip, palate, and orbit." No mention is made in this work or apparently in any other of the molar glands or the region in which they are found.

Anatomy of the Molar Glands.—The molar glands are about five in number and lie on the outer surface of the buccinator muscle grouped round the site of perforation of the latter by Stenson's duct. (Fig. 1).

FIG. 1.



The anatomy of the molar glands. (Modified from a specimen in the London Hospital Museum, by courtesy of Prof. William Wright.)

Their ducts also pierce this muscle and open into the vestibule of the mouth (Fig. 2). The glands are mainly mucous in character and are developed as solid buds of the buccal epithelium which grow outwards through the buccinator muscle branching frequently and becoming canalised.

It will thus be seen that the parotid gland may be looked upon as a molar gland that has grown backwards over the masseter muscle and become somewhat specialised in function.

Pathology of Mixed Tumours.—The pathology of mixed tumours has given rise to considerable discussion, therefore it will suffice to mention the following theories of origin: (*a*) They are teratoblastomata—i.e., tumours arising from a pluripotent cell which is capable of producing both epithelial and connective tissue structures. (*b*) They are endotheliomata. (*c*) They are developed from embryonic remnants of the branchial arches. (*d*) They are adenomata which may undergo malignant change. (*a*) and (*b*) are the two most popular theories.

Microscopically mixed tumours present myxomatous tissue, fibrous tissue, immature cartilage, and columns of cells which may be epithelial or endothelial in origin.

Clinical Features.

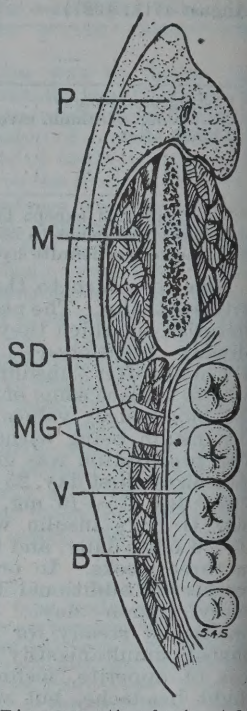
Mixed tumours usually occur in young adults and form slowly growing, firm, lobulated, sharply defined, freely movable swellings. They may grow slowly for many years, but at any time (even at first appearance) may take on rapid growth and infiltrate surrounding structures. The following cases may be cited as examples of mixed tumours arising in the molar glands:—

CASE 1.—A man, aged 20, was admitted to the Walthamstow, Wanstead, and Leyton Hospital under the care of Mr. J. H. Barrs with a lump in the left cheek. It had been present for two years but had been growing rapidly for six weeks. The lump was hard, the size and shape of a walnut, not attached to the skin nor the mucosa of the mouth; it extended forward almost to the angle of the mouth (Fig. 3). The tumour was removed by a horizontal incision through the mucosa from which it was found to be separated by a layer of muscle, the buccinator. It shelled out easily except at one place antero-inferiorly where it was adherent. On section there was a capsule from which some rather indefinite fibrous trabeculæ passed inwards. Between these there was gelatinous substance, a small yellow area 0·6 by 0·8 cm., and a red area of similar dimensions.

The microscopical report, by Dr. A. B. Bratton, was as follows: "The section shows a polygonal-celled carcinoma. The carcinoma cells resemble the epithelial cells of a mixed tumour. The connective tissue is abundant and fibrous, but in one area is hyaline and somewhat suggests fibro-cartilage. Therefore the carcinoma probably arose in a mixed tumour."

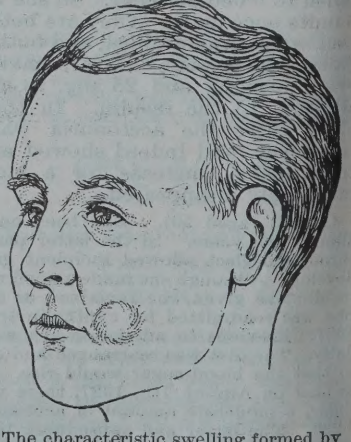
About one month after operation the tumour recurred, growing rapidly, infiltrating the tissues of the cheek, and becoming adherent to the mucosa and skin. X ray treatment was employed but apparently had no effect. The greater part of the tumour was, therefore, excised and radium inserted. This, however, will probably not prevent recurrence of such a highly malignant tumour. Dr. Bratton reported that microscopically the recurrence was a polygonal-celled carcinoma in which the carcinoma cells resembled the epithelial cells of a mixed tumour.

FIG. 2.



Diagrammatic horizontal section showing how Stenson's duct and the ducts of the molar glands pierce the buccinator muscle to open into the vestibule. P. = Parotid gland. M. = Masseter. S.D. = Stenson's duct. M.G. = Molar glands. V. = Vestibule. B. = Buccinator.

FIG. 3.



The characteristic swelling formed by a mixed tumour of a molar gland (Case 1).

CASE 2.—A woman, of 28, was admitted to the London Hospital under the care of Mr. W. S. Perrin with a lump in the left cheek. It had been growing slowly for five years and was quite painless. The lump was one inch in diameter, fairly hard, and had a well-defined edge; it extended forward to the angle of the mouth and was not attached to the skin or mucosa. It was removed by a horizontal incision through the mucosa and shelled out easily. Dr. W. W. Woods reported that microscopical examination showed a mixed tumour of a salivary gland. There has been no recurrence since operation which was one year ago.

I wish to express my indebtedness to Mr. J. H. Barrs, Mr. W. S. Perrin, Dr. W. W. Woods, and Dr. A. B. Bratton.

Clinical and Laboratory Notes.

GONORRHŒAL URETHRITIS IN MALE CHILDREN.

REPORT ON FOUR CASES.

BY B. BUCKLEY SHARP, M.B., B.S. LOND., M.R.C.S. ENG.,

ASSISTANT VENEREAL DISEASE DEPARTMENTS, ROYAL NORTHERN HOSPITAL AND THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

Gonorrhœal urethritis in males before the age of puberty is a rare occurrence. In the literature of the last 10 years I have found reference to only 45 cases. Alterthum,[1] in America, states that Stümpke collected seven cases and Wolbarst 22 cases. He himself reports 14 cases occurring between 1919 and 1925. In this series the ages ranged from 4 to 13 years. There were no infections of the posterior urethra or rectum, and no complications. As regards their ætiology, he divided his cases into the following four groups: (*a*) Direct genital contact; three cases, in one of which the source of infection was a domestic servant; while in each of the other two cases the source was a female child. (*b*) Sleeping in the same bed with infected persons, but no proof of genital contact; four cases. (*c*) Infection present in other members of the same family, but no evidence of genital contact, and no occupation of the same bed; four cases. (*d*) Source unknown; three cases.

Dryer and Rinhard each report a case of urethral infection in newly born male children 4 and 10 days old respectively, in one of which epididymitis developed. Erich Langer, in Berlin,[2] in a general survey of the subject, agrees that gonorrhœal infection in boys may occur without sexual intercourse. The other possible modes of contagion that he mentions are by sponges, towels, and lavatories, or by bathing with another infected child, which are also the ways by which female children are commonly infected. In older boys direct rectal infection may occur as the result of homosexual practices by men, direct rectal infection in younger male or female children being usually due to the use of infected thermometers or enema nozzles.

Clinical Records.

The cases that I have to report have occurred as follows:—

CASE 1.—A. B., aged 10, attended the Royal Northern Hospital on Dec. 10th, 1920, stating that he had had a urethral discharge and pain on micturition one month previously. One week before his first attendance he had been circumcised; so apparently the cause of the discharge had been attributed, in the first place, to balanitis arising from phimosis. He slept alone, and no source of infection was traced. Gonococci were found in the urethral discharge. He was given an alkaline mixture and irrigations of the anterior urethra with 1/8000 potassium permanganate solution. On Jan. 1st, 1921, he complained of pain in the back; but the discharge ceased that day, and the urine was clear two days later. After five days, however, pus was again found in the urine. On Jan. 19th the prostate was found to be enlarged and tender, and a periurethral abscess had developed proximal to the peno-scrotal junction by Jan. 26th. As this abscess did not drain into the urethra, and remained in statu quo in spite of fomentations, it was incised from the outside early in February. A sinus persisted, and did not finally close until July 7th after the passage of bougies, size 3–7 English, on many occasions. The prostate was found to have returned to normal on April 18th, though no special treatment had been applied to it and no irrigations of the posterior urethra given. The patient was finally discharged on Feb. 13th, 1922, bougies having been passed at increasing intervals up to that date.

CASE 2.—C. D., aged 6, attended the Hospital for Sick Children on June 25th, 1924, with œdema of the prepuce (a long one) and a purulent urethral discharge containing gonococci. Micturition was painful. The mother stated that the discharge was first seen four days before. The patient lived with his grandmother, and four young maiden aunts resided in the same house. He had two sisters, aged 5½ and 4 respectively, who were normal. He had been attending an infants' school, in which were male and female infants together. Irrigation of the anterior urethra with 1/8000 potassium permanganate solution was carried out daily. This was changed to 1/4000 oxycyanide of mercury after three weeks, at which time the first urine after anterior irrigation was found to contain pus, indicating that the posterior urethra was infected. Irrigations of the posterior urethra were then started. Five weekly doses of a stock gonococcus vaccine, ranging from 2½ to 50 millions, were given. The discharge ceased after five weeks of treatment, and the boy was allowed up. One week later the discharge recurred, and the anterior and posterior irrigations were recommenced. In addition, Nos. 3 and 4 English bougies were passed down as far as the compressor on one occasion. The prostate, which at this age is very small, felt normal throughout the disease. By Sept. 2nd all signs had permanently cleared up, and the patient was discharged as cured on Sept. 25th, after three months in hospital.

CASE 3.—E. F., aged 5½, attended the Hospital for Sick Children on Nov. 27th, 1924, with a urethral discharge containing gonococci. Pain on micturition had been present for five days, and the discharge for three days. He had a long prepuce with œdema and acquired phimosis. This boy lived in the same street as Case 2 and attended the same school. The source of infection may have been the same, though Case 2 was cured two months before Case 3 was attacked. The latter had two uninfected brothers and no sisters. Treatment consisted of first subpreputial, then anterior, and, after three weeks, both anterior and posterior irrigations with potassium permanganate solution, the strength being gradually increased from 1/6000 to 1/4000. No vaccine was given. The discharge had ceased in five weeks, but the urine still contained pus. Bougies, Nos. 6 and 7 English, were passed as far as the compressor on one occasion only, and three days later the urine was clear and remained so. The patient was discharged eight weeks after the commencement of treatment.

CASE 4.—G. H., aged 13, attended the Royal Northern Hospital on Nov. 4th, 1926, with a urethral discharge of five days' duration which was associated with pain to begin with. Gonococci were present. He had a long prepuce and congenital phimosis. He had been attending school, and slept with his brother, aged 10, who was not infected. He had two sisters, aged 15 and 17 respectively, who were alleged to be normal. The mother denied ever having had any vaginal discharge. He was treated in the same way as Case 3 except that 1/4000 oxycyanide of mercury was substituted for potassium permanganate. He still had a discharge five and a half weeks after the onset of treatment, so that a No. 15 French bougie was passed as far as the compressor. This increased the discharge temporarily, and gonococci were again found. Passage of bougies Nos. 15 to 17 French on two subsequent occasions cleared up all signs permanently. No changes were observed in the prostate. The patient was discharged after ten weeks.

Commentary.

In none of the above cases was the mode of infection or its source elicited. Cases 2 and 3 may have had a common source of infection. In each case there was a long—and in one case a tight—prepuce at the time of onset. Thus the gonococcus must have gained access to the preputial sac before entering the urethra in the case of congenital phimosis, and probably also in the other cases. This would tend to show that the contact with the source of infection was an intimate one. We have no proof that direct genital contact is necessary to produce infection in a boy, the opinion of other writers on the subject being to the contrary, though I have never come across a case in a man, after taking many hundreds of histories, where the infection had been acquired accidentally. We know, however, that in female children accidental infection without genital contact is the rule rather than the exception. Females over the age of puberty are much less susceptible to accidental infection, as the vulva and vagina (as opposed to the urethra and cervix) become resistant to the implantation of the gonococcus.

Two ways in which, in the case of boys, direct genital contact may come about are, firstly, seduction by an adult woman, of which I have come across two cases, though in neither of these was there any infection transmitted; and, secondly, attempts at sexual congress between male and female children. These attempts are probably imitative, and occur among the children of poor parents with whom they share the same bedroom and often the same bed. I have never

[1] Deutsche Med. Wochenschr., April 30th, 1926.
[2] Geschlechtskrankheiten bei Kindern, 1926.

heard of a case of gonorrhœa in a boy whose parents were well-to-do.

As regards treatment, this is approximately the same as in the case of an adult male. Prostatic massage would appear never to be required, while other complications such as iritis and arthritis do not occur owing to the rarity of prostatic infections. Epididymitis has only been once recorded, and then in a case of a newly born male infant. There has been only one case of periurethral abscess recorded (Case 1 in this series). Infection of the urethral glands undoubtedly occurs, and therefore it is necessary to pass a bougie along the anterior urethra once or twice towards the end of treatment.

Two to three months is the average period required for cure.

I am indebted to Mr. Kenneth Walker for permission to publish the cases that came under my care at the Royal Northern Hospital, and to Dr. D. Nabarro with regard to the cases at the Hospital for Sick Children.

A CASE OF
COMPLETE ABSENCE OF GALL-BLADDER AND EXTRAHEPATIC BILE-DUCTS.

BY NORMAN H. HILL, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN AND TO THE METROPOLITAN HOSPITAL, LONDON.

THE following case is, I think, worthy of record as illustrating one of the rarer forms of congenital anomalies of the biliary tract.

A female infant, aged 4 months, was admitted to the Belgrave Hospital for Children on account of jaundice. She was an only child; the parents were alive and in good health; there had been no miscarriages and no history of tuberculosis.

Past History.—Full-term child; normal labour. Jaundice was noticed on the fourth day and persisted. The child was breast-fed and gained weight steadily, the only digestive disturbance being a little flatulence and vomiting, which occurred a fortnight before admission and lasted only two days. The stools were described as white in colour, but became very dark for a day or two about three weeks before admission to hospital. The parents did not notice anything abnormal in the colour of the child's urine, and stated that the napkins had not been stained.

On *examination* the child seemed well nourished, her weight being 11 lb. 12 oz. The skin was of a moderately deep icteric tint and the sclerotics were of a deep yellow colour. There were no cutaneous hæmorrhages and the mucous membranes were rather pale. The fontanelle, heart, and lungs were normal. The abdomen was somewhat enlarged. The liver could be felt three fingers-breadth below the costal margin; its edge was sharp and hard. The spleen was palpable.

During the four days following admission the child seemed well and contented and gained 2½ oz. in weight. Breast-feeding was continued. The stools were consistently pale and contained no bile pigments, whilst the urine was dark and contained both bile salts and pigments.

Examination of the blood gave the following results: Red blood corpuscles, 4,892,000; white blood corpuscles, 13,000; hæmoglobin, 77 per cent.; colour-index, 0·79. Films showed some anisocytosis and poikilocytosis. The differential count showed: Polymorphonuclears, 42·2 per cent.; lymphocytes, 46·6 per cent.; myelocytes, 2·8 per cent.; and eosinophils, 8·4 per cent. The fragility of the red corpuscles was normal. Van den Bergh's tests gave a biphasic reaction.

Some slight ecchymosis occurred around the points from which blood was taken, but there were no gross hæmorrhages. The jaundice seemed to vary in intensity from day to day slightly but definitely. On the fifth day the child had a profuse melæna, two of the stools giving a strongly positive guaiac and benzidine test, and showing red corpuscles microscopically. On the sixth day she was paler and weaker and had two quite copious hæmatemeses. From this time onwards there was much melæna and frequent hæmatemeses. The child's condition rapidly deteriorated and she died on the tenth day.

Findings at Autopsy.—With the exception of bile staining no abnormality was found in any of the organs other than the liver and its appendages. There was no ascites. Examination of the brain was not permitted.

The liver was enlarged and of an olive green colour. It was very hard and its surface was definitely granular. There was some irregularity of the anterior border of the left lobe. The duodenum was normal, the papilla was present, and the pancreatic duct was patent. The lymphatic glands which drained the liver were all deeply bile-stained. The gastro-hepatic omentum was in its normal position, as were also the portal vein and the hepatic artery. No trace, however, of the common bile-duct could be found, not even the fibrous cord which so often represents it in these cases. There was no cystic duct, no gall-bladder, and no extrahepatic bile-ducts, neither were any remains of these structures discoverable. The spleen was only slightly enlarged, although easily palpable during life. The pancreas appeared normal.

Microscopical Examination.—The liver showed an extensive cirrhosis mainly in the portal areas in which bile-ducts were numerous. Some of these were distended with bile and some of the larger ducts showed desquamation of their lining membrane and infiltration of the surrounding tissue with small round cells. Areas of liver tissue were cut off as in portal cirrhosis, but bile could be seen in the finer biliary radicles, some of which were considerably distended. Some areas of liver had undergone acute necrosis and these were particularly bile-stained. The pancreas showed a slight degree of fibrosis, but otherwise appeared normal. The lymph glands and other organs showed no abnormality.

Comments.

The abnormality most often reported in cases presenting similar symptoms is a common bile-duct impervious or deficient at some part of its course. Other cases described range from these conditions to complete absence of all extrahepatic bile-ducts and gall-bladder, intermediate cases presenting every variety of abnormality. J. B. Holmes [1] has collected over a hundred published cases of congenital obliteration of the bile-ducts and has given diagrams of the conditions found.

The pathology of the condition has been disputed, and several different theories put forward to account for it. Syphilis and fœtal peritonitis have each been held responsible, though why the results of these two conditions should be limited to the liver and its appendages it is difficult to see. John Thomson [2] considered that there was, to begin with, a congenital malformation of the bile-ducts due to defective development, and that interference with the outflow of bile caused catarrh and finally blocking and obliteration of the ducts, the cirrhosis of the liver being a secondary manifestation. Sir Humphry Rolleston and L. B. Hayne [3] regarded the condition as primarily due to poisons derived from the mother and conveyed to the liver of the fœtus, where they set up a mixed (portal and biliary) cirrhosis and a descending obliterative cholangitis analogous to obliterative appendicitis. In support of the theory of the maternal toxin is the fact that there are several recorded cases of parents having more than one child similarly affected, and in Thomson's series there were two such cases. In no case, however, has the mother shown evidence of such toxins.

Stanley Wyard [4] suggests that the condition may be due to an ascending cholangitis due to a toxin which is a constituent of a pathological liquor amnii. Holmes says:—

"It would seem that the cause of congenital atresia of the bile-ducts must be sought, as a rule, in a faulty development from the primary tissues. What the causes of this are we scarcely know. They are doubtless the same as those operative in the production of atresias of other tubular structures."

Leonard Parsons and Evelyn Hickmans [5] consider that

"whatever be the cause of the condition it is one which attacks the liver parenchyma at as early a stage as the bile-ducts, and offers definite evidence that the whole process may be an intrahepatic one."

As regards treatment Holmes suggests that as in 16 per cent. of all the cases he collected the anatomical relations were such that operative relief was theoretically possible, the biliary tract should be explored as soon as the diagnosis is sufficiently established, with a view to making an artificial opening for the bile to reach the duodenum, in consideration of the otherwise hopeless nature of these cases.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Continued from p. 608.*)

SECTION OF PATHOLOGY AND BACTERIOLOGY.

WEDNESDAY, JULY 20TH.

THIS Section met under the presidency of Prof. J. LORRAIN SMITH (Edinburgh). On the first day Dr. ARCHIBALD LEITCH (London) opened a discussion upon

GROWTH IN ITS PATHOLOGICAL RELATIONS.

He pointed out that in extra-embryonic life, in general, the reproductive powers of the cell become markedly restricted, this varying in degree with different tissues—the power of growth sometimes being absent and at other times constantly present. In the body this process of cell production, however manifest, is always under rigid control and at no time lawless. Although, as tissue culture experiments show, this proliferation may become limitless in an alien environment, when restored to the body the cells once more conform to the very rigid laws controlling their multiplication. In wound repair the more obvious process was that of proliferation, but that of inhibition, controlling the amount of new tissue produced, was hardly less mysterious. The boundaries between reparative growth, hyperplasia, and neoplasia were ill-defined and no rigid separation was possible between benign and malignant tumours. He held that the cell in neoplasia had no altogether new properties differentiating it from those found in reparative processes, which led him to the conclusion that tumours arise only in those cells capable of multiplication in post-embryonic life, and that if other elements than these are present, they are derived from fœtally segregated cells in Cohnheim's sense of the term. It was possible that in many of these apparent exceptions the appearance of such tissues as bone and cartilage were due to the rather remarkable process of metaplasia possessed by the connective tissue cell. The totally different behaviour of malignant cells in the body could only be explicable along two lines—either that they had become associated with an adjuvant—the parasitic theory lately developed by Gye and Barnard—or that they had developed in an advanced degree an already existing property. Referring in detail to the former hypothesis, he declared that it was entirely based upon experiments carried out with a single variety of growth, the Rous sarcoma of fowls—a growth whose true nature had never been agreed upon. Its properties were peculiar and were shared with no other form of neoplasm. Gye and Barnard's thesis turned upon the true sarcomatous nature of this growth, and also upon their claim to have cultivated a virus from other neoplasms; if either fact were incorrect their theory became void. With regard to the first point, the peculiar characters of this tumour distinguished it from all other growths. Whilst unable to give it a definite apellation, Dr. Leitch did not regard it as a sarcoma but rather as a spreading necrobiotic process of unknown origin. Even in the smallest nodules of the growth the necrotic process followed fast upon the neoplastic. Turning to the experiments in which the activation of chemically inactivated extracts was produced by what were presumed to be cultures of the virus, Dr. Leitch remarked upon the natural great variability in activity of the Rous tumour extracts. Two injections of the same material—treated by chemical destructive agents so as to reduce its activity to near vanishing point—injected into the same bird might give totally different results; the one a tumour, the other nothing. Many other conflicting factors were at work which could determine the appearance or non-appearance of tumours when extracts of almost extinguished activity were used. The borderline between total destruction of the activity of extracts by chemicals and the damage necessary for the removal of the virus portion was narrow. In some experiments the so-called chemical factor alone gave rise to tumours, in others the combination of the two supposedly essential factors failed to produce a tumour. In conclusion, the speaker held that there had been no clear demonstration of a dual nature of the infecting agent and, therefore, no demonstration of a virus of cancer. The one other form of mouse sarcoma which, according to Gye and Barnard, was filtrable had not shown this property in the hands of other investigators.

Cell Proliferation.

Prof. ROBERT MUIR (Glasgow) dealt with the processes of cell proliferation in general. The subject, he said, had been extended of recent years by means of experiments upon tissue culture and upon the filtrable viruses. Dealing with the process of repair, he criticised the assumption of special substances (trephones) being concerned in this process. There was no evidence for such a phenomenon under normal conditions within the body, and a strict application of the results of tissue cultures to the processes of repair was not permissible. When proliferation stopped, in the healing of a wound, was it to be assumed that the supply of such substances also stopped simultaneously? The probability was that the supposed trephones were only food substances. In hypertrophy the demand for overgrowth must originate in the cells themselves. Hyperplastic conditions might pass over into tumour formation, as in the hepatomas and carcinomas arising in cirrhosis of the liver; in these cases the neoplastic focus would appear to start in the centre of the hyperplastic area and away from the reactive process. Dealing with tumours, he said that the future method of division was likely to be into filtrable and non-filtrable groups; the former group, though now small, might grow more extensive. In the large group of non-filtrable tumours he differentiated (*a*) those due to irritation, and (*b*) those attributable to developmental influences. The former followed upon a long history of irritation and were simple in their histological structure. The latter were often complex and were to be recognised rather by their character than by their site of growth; they were tumours which often appeared at an early age, as, for example, the neurocytomas and the blastocytomas. It was quite possible for apparently similar tumours, evolving in the same way and clinically indistinguishable, to originate in both of these classes, as, for example, the hepatic carcinoma of cirrhosis and a case he had recently observed of a malignant hepatoma in the otherwise healthy liver of a child.

Prof. SHAW DUNN (Manchester) referred to the difficulty in framing a definition of tumours so as to exclude such conditions as Hodgkin's disease and mycosis fungoides. The very definite effect of irritants, confirmed by animal experiments, provided a means of understanding the genesis of certain growths; those of the mouth and possibly many others of the alimentary canal were attributable to this influence. Other tumours seemed to show a capacity for originating in damaged organs—e.g., those of the liver referred to by the previous speaker—the hypernephromata, which seldom seemed to take origin in an entirely healthy kidney, and the epitheliomata originating in scars. The frequency with which malignant tumours developed from simple ones was uncertain, but the evidence in many cases was clear. Polyposis of the large intestine was a case in point; this was often a familial disease and in about 50 per cent. of the subjects cancer developed. Prof. Shaw Dunn cited other examples of hereditary and familial conditions associated with carcinoma. Of special interest, though a rare condition, was xeroderma pigmentosa; in this condition light was known to be the accessory factor in producing carcinoma and could be controlled.

Prof. M. J. STEWART (Leeds) discussed the question of tissue displacements and their connexion with tumour growth. The most widely known of these was the adrenal rest, which, however, was frequently met with in situations other than the kidney. In a recent large series of post-mortem examinations he

had noted eight of these formations in the liver, six in the broad ligament, five in the spermatic vessels, one in the epididymis, and one in the testicle. These findings were of importance in connexion with the Grawitz view of hypernephromata, against which he summarised the following facts: (1) that some of these tumours show lumen formation, either with or without the adrenal type of cell; (2) that true hypernephromata do not appear to arise elsewhere than in the kidney; (3) that they are not associated with virilism which as Glynn had shown is so prominent a feature of true adrenal tumours; and, finally, (4) that the Grawitz tumour is equally common at both poles of the kidney, whilst the adrenal rest is especially found at the upper pole. Prof. Stewart further described the epithelial heterotopias of the alimentary tract and discussed the possibility of their being the origin of malignant disease; for this he contended there was no evidence. He thought that the occurrence of teratomata, apart from those of the sexual glands, gave general support to Cohnheim's theory.

Prof. E. H. KETTLE (Cardiff) thought that the discussion came at a most difficult stage in our knowledge of tumour growths. Some years ago most of the more disturbing facts of the present day were unknown and some years hence their bearing on the general problem would doubtless be better understood. He felt great doubts about the supposed essential similarity of the processes of innocent, malignant, and hypertrophic growth. Growth and proliferation were not identical processes. The work of T. S. P. Strangeways tended to show that mitosis in some cases was a reaction of the cell towards an altered environment and that in this plastic state it is more adaptable. Hence different types of cell proliferation doubtless exist, diverted towards different ends, and similar distinctions may be ultimately be drawn amongst tumour processes. He refused to regard the pathological investigation of the processes of abnormal growth as a dead subject, and considered that renewed application of the analytical method to such conditions might lead to an ultimate recognition of immediate causes.

The PRESIDENT, in closing the discussion, said that he was in agreement with Prof. Kettle that in growth there were many phases. In the division of certain cells—as, for example, those of the rete malpighii—one of the progeny was destined for growth and differentiation, the other retained the capacity for further pululation. There were therefore two processes to be distinguished—growth and proliferation. It was an unanswered question in which of these phases cancer affected the cell.

THURSDAY, JULY 21ST.

The meetings on the second and third days of this Section were conjoint meetings with the Section of Comparative Medicine. On July 21st Prof. T. J. MACKIE (Edinburgh) presided over a discussion on

IMMUNITY.

Dr. R. A. O'BRIEN (London), in opening the discussion, said that he desired to deal especially with the practical or applied side of the subject and to review the recent solid achievements and future problems. It might be said that among the achievements of modern medicine were the practical abolition, from this country at all events, of typhus, cholera, dysentery, typhoid, and plague. Here credit must be given chiefly to the hygienist and sanitarian, with the immunologist in the second place, and the clinician last. In the future he believed that most credit for advances would go to the immunologist, who to his other weapons was adding that of the experimental investigation and control of epidemics. The importance of food factors in this connexion was very great, since it was frequently found that the germs of epidemics could remain living, but inactive, in animal communities provided the nutrition of these was duly maintained; but when diet became insufficient or ill-balanced an outbreak of infection speedily followed. The hollow needle, as a weapon of offence and defence, was already firmly established both in animal pathology—for example, in swine fever, roup, rabies, rinderpest, and in the human subject in connexion with enteric prophylaxis, tetanus, diphtheria, and rabies. Reviewing the agents utilisable for this purpose he instanced preventive vaccines; these had sometimes been employed in the living state, but which in the future he considered would be universally replaced by dead vaccines. The latest advance in this direction was the use of Calmette's B.C.G. in tuberculosis; about the value of this agent very contradictory opinions had been expressed. In all vaccines of this type there was a deplorable lack of agreement as to dosage and a total absence of any official standards of activity. A second method of producing immunity was by the injection of bacterial filtrates. In nurses employed in fever hospitals the introduction of this method of affording protection against scarlatina gave striking results; the same could be said of diphtheria. In veterinary pathology the method was the one now employed in connexion with braxy and black-leg. A third method was the use of toxoids and allied substances, which were found to give a solid immunity in diphtheria. The use of toxin-antitoxin mixtures had been largely developed, extended, and varied since its introduction by Theobald Smith in 1907. In applying this method it was all-important to choose a correctly balanced mixture of toxin and antitoxin. Excess of the one would produce disastrous results and of the other merely passive immunity which was not the desideratum. The position might be well illustrated by the results of giving immune serum (convalescent) to children in measles. Administered early in the incubation stage it prevented any development of the virus and conferred a purely passive immunity, merely postponing the evil day of infection. Given when the disease was declaring itself it had little but a slight therapeutic action. Given in an intermediate stage it had the effect of aborting the disease whilst such infection as did take place induced an active immunity in the child, sufficient to guard against future infections. In discussing some of the current practical problems of immunisation the speaker referred to the puzzling phenomenon of local infections occurring in highly immunised animals; this phenomenon, he said, was well illustrated in anti-pneumococcus immunity.

Prof. C. H. BROWNING (Glasgow) commented upon the enormous growth of the literature of immunity in recent years. The study of the serum reactions dated from the discovery by von Behring of antibody in this cell-free body fluid. Prof. Browning proposed to discuss (1) antigen-antibody reactions, their phenomena and the questions arising out of them; (2) the part played by immunity in chemotherapeutic action; and (3) Ehrlich's receptor theory. Antigen antibody reactions were usually evidenced by some physical alteration in the mixture and hence a series of "indicators" might be recognised and correlated with the reaction; amongst these "indicators" lipoids played an important part though not an essential one. With regard to the nature of anti bodies, there was some evidence that immune bodies might differ qualitatively as well as quantitatively immature hæmolysin having properties different t those of the mature product. The essential factor i calling out the antibody was the injection of th antigen, but in any conception of the process th occurrence of natural antibodies must be borne i mind; their presence was in some cases entirel inexplicable, and they might be termed "metaboli accidents." He believed, from evidence brough forward by a variety of workers, that the commo prototype of immune antibodies exists normally i blood plasma, in a relatively undifferentiated stat and that it undergoes a specific modification d development in the process of immunisation with a antigen. The scanty evidence available went to sho that antibodies were definite substances in the serum but that the complement might more correctly b regarded as a physical state of that body. Recentl there had been a tendency to identify the reticul endothelial system with the production of antibodie but the results of experiments were inconclusive an

attempts to lower an animal's resistance by "blocking" the cells of this system with dyes had showed that this result had not the effect in diminishing resistance which it should have if this system were of prime importance. Antigens had, up till recently, been looked upon as protein in nature, but some results had been obtained showing that lipoids and carbohydrates might exert this function. The nature of specificity was still obscure, but H. H. Dale's experiments with racemised albumins showed that specificity was connected in some cases with the order of the amino-acid linkage. In regard to chemotherapy, animals cured of trypanosome infections frequently showed some degree of subsequent immunity, which could be produced by this means alone. The immunity response, therefore, seemed to be intensified and intimately linked with the drug's action, since other trypanosomicidal agents did not produce the same result. In conclusion, Prof. Browning urged the restoration of Ehrlich's receptor hypothesis to something approaching its former pride of place, since he maintained that in its broader aspects and shorn of its later-day trimmings it formed the most satisfactory working hypothesis for the manifold facts of immunity.

Prof. ROBERT MUIR gave a general review of the problems of immunity; the phenomenon, he said, involved changes in the living cells and in the serum, to the last of which most of the attention given to the subject had been paid. A multitude of laboratory reactions, agglutination, precipitation, complement fixation, &c., had been evolved, most of which were the physical evidences of combination between antigen and antibody. This was the essential fact of these reactions and, on the whole, its nature appeared chemical rather than physical. The varied types of antibodies had received various names for convenience, but Prof. Muir suggested that the serum antibodies were not a set of disjointed entities but a single entity with distinct moieties. A similar conception might be applied to complement. Differences in antigenic action were due to minute differences in structure of the antigens. There was no common antibody for bacterial protoplasm, but closely related bacteria were antigenically distinct and similar individual differences might be met with between the cells of animals of the same species, as had been shown by Ehrlich and Morgenroth for the isolysins of goats. Did the body produce something corresponding to every possible variation of antigenic substance as Ehrlich's hypothesis suggested? Prof. Muir discussed the possibility of the dissociation of antigen and antibody from combination in the body and adduced evidence for the occurrence of this dissociation. The local immunity of tissue, upon which Besredka had recently insisted, was an important consideration and worthy of full investigation.

The Relation of Sensitisation to Immunity.

Prof. E. L. OPIE (Philadelphia) spoke of the relation of sensitisation to immunity, which was a very puzzling phenomenon. In animals in which an injection of antigen produced the Arthus phenomenon, the antigen became fixed at the site of this reaction and did not pass into the body; this was therefore a protective effort guarding more vital organs from the dangerous results of anaphylaxis. The phenomenon was capable of reversal and an animal could be sensitised with antigen so that it showed the phenomenon following on a local injection of antibody. A like result was obtainable in the case of generalised anaphylaxis. The conclusion was that wherever and whenever antigen and antibody met, a reaction occurred the nature and extent of which was determined by the physiology of the tissue involved, so that such diversified results as the Arthus phenomenon or general anaphylaxis might take place. He thought that all immunity phenomena were matters of importance to the animals concerned and doubted if such a thing as a "metabolic accident, described by Prof. Browning, ever occurred.

Colonel W. F. HARVEY (Edinburgh) detailed a series of experiments carried out by him in India in order to study some of the factors influencing the immunity conferred by vaccines, with especial reference to reinoculation. The work had been done upon pigeons, the organism of fowl cholera being used as the infecting agent. He showed that in the conditions described immunity only lasted for about five months and that for reinoculation a dose considerably smaller than the initial one gave a satisfactory result; further, that the reinoculated animals retained their subsequent immunity for a longer period than those receiving a single treatment. He suggested that an animal once inoculated always bore the impress of this procedure and never afterwards reacted quite like a normal one.

Prof. D. C. MATHESON (Edinburgh) spoke briefly upon the question of practical methods. Living vaccines were used in immunisation against epizoötic abortion and also in pleuro-pneumonia in bovines. The general principle was to introduce the virus at a site remote from that in which it normally flourished, and where conditions must be considered unfavourable for its life. The procedure of immunising the mother in lamb dysentery was a new one. In the bacillary white diarrhœa of fowls the carrier birds could be detected by the agglutination test and healthy chickens reared from the eggs of uninfected birds.

Dr. HEDLEY WRIGHT (London) said that acquired immunity was generally the result of antibody activity, but in recent work there was a strong suggestion that a local cellular immunity might exist. In pneumococcal infections the general immunity appeared rapidly, whilst the demonstration of antibodies was difficult; this was simply a result of deficiencies in technique. Changes in the way in which organisms grew in the blood of the animals gave earlier evidence than the accepted immunity reactions. In his opinion the evidence for the existence of a cellular immunity was slight. Dealing with the local infections of highly immunised animals as, for example, the cardiac valves in ulcerative endocarditis, the organisms in this case were relatively avirulent, and the immunity of the patient high. The inability of the latter to deal with the organisms was, in the speaker's view, an anatomical one, the organisms on the cardiac valves being shielded from the ordinary attack. Septicæmias were of different types in accordance with the state of the subject's immunity. In some cases the organisms multiplied in the blood, in others, as in the case of endocarditis, they tended to die out.

Dr. W. H. ANDREWES (Ministry of Agriculture) discussed immunity in veterinary medicine. The vaccine of contagious abortion was eliminated rapidly unless the animal was pregnant, when the organisms persisted in the uterus, or unless the mammary glands were active, when the organisms persisted over long periods in the milk. In trypanosome infections a chemotherapeutic agent might be curative in an infection of a normally resistant species, but inert in a susceptible one. Hygienic measures were largely responsible for improved conditions amongst animals in tropical countries and in South Africa horses, sheep, and goats could now be kept in many districts in which formerly this was impossible. In veterinary medicine the economic problem was the directing factor, and therefore the pole-axe was often preferable to the immunising syringe. In such diseases as glanders and rinderpest, in this country, the use of the former instrument was advisable.

Prof. MACKIE said that one of the chief obstacles to further advance in this field was our lack of information as to the weapons of offence and defence possessed by the organism as distinct from the host. Investigations tended towards an elaborate analysis of antibody reactions and the main problem was lost sight of. Natural immunity, a most important phenomenon, could only rarely be attributed to this means of defence and solid immunity might coexist with an absence of antibodies. He did not think that the field of colloidal chemistry, into which present investigations were leading, was one in which much knowledge could be gained of the processes of resistance to disease.

FRIDAY, JULY 22ND.

On the third day of the meeting, Principal O. CHARNOCK BRADLEY being in the chair, Prof. BASIL BUXTON (Cambridge) opened a discussion upon the

ASPECTS AND PROBLEMS OF COMPARATIVE MEDICINE.

He said that at the present time general agreement existed as to the value and desirability of the study of comparative medicine. By many this was regarded as a new movement, but it was not so. Actually steady progress was going forward in comparative medicine, but the necessities of modern medicine, leading to division of labour and specialisation, resulted in widespread general ignorance of what had been and was being done. Great progress had been made especially in the tropics, where, under the pressure of economic conditions, adequate facilities had been forthcoming for the investigation of diseases caused by protozoa and invisible viruses. In comparative pathology that coöperation between specialists in human and animal medicine was essential. Such collaboration need not be limited to the study of diseases common to man and animals, although where such a relationship existed it enormously facilitated the investigation of such diseases. Tuberculosis and the study of tumours were notable examples; everyone was familiar with the great gain to man accruing from the study of the variolas of lower animals. It happened sometimes unfortunately from the experimental point of view that organisms causing disease in man were non-pathogenic to the lower animals. Here a comparative study of closely resembling conditions, such as canine distemper and influenza, might yield valuable results. Again, the investigation of animal diseases due to invisible viruses, rinderpest, foot-and-mouth disease, and distemper, were yielding methods of immunisation which might prove of great interest and utility in human disease. As an outcome of the study of the anaerobic infections of man, which had been largely stimulated by the war, he predicted a more intensive and fruitful study of these in the lower animals. It was probable again that certain diseases in animals kept under apparently normal conditions were due to deficiency in accessory food factors. It was still doubtful as to what extent experimental results with one animal in this connexion were applicable to other animals and to man. White rats were little affected by the absence of vitamin C from their diet, but bred ill under such conditions. In general the picture of deficiency diseases varied with the species. More important than the actual deficiency diseases themselves were conditions resulting from minor degrees of deprivation, leading to lowered resistance to bacteria; under such conditions organisms normally present in the animals and producing no ill-results, might assume pathogenic properties. The importance of mineral metabolism was great in animal pathology; pastures with a low mineral content being of little nutritional value for sheep, the reproductive capacity of these animals grazing on such pastures was low and the percentage of deaths amongst the offspring high. Amongst other facts recently discovered from metabolic investigations was the realisation of the bacterial defence conveyed to young animals by colostrum; there was a high iodine content in this material and the feeding of iodide to mares would prevent joint-ill in foals. Prof. Buxton thought the question of the relation of iodine to the immunity of the newly-born animal worthy of investigation. Another subject which offered a wide field for research was the physiology of reproduction, which was being studied at the Animal Nutrition Institute at Cambridge. One of the largest subjects in human medicine was that of immunity, and in particular artificial immunity. Here animals were essential because only on them could the necessary critical experiments be made, whilst the subject was of no less importance in veterinary medicine in the control of epizoötic and enzoötic diseases.

Dr. ANDREW BALFOUR (London) commented upon the manifold problems connected with the subject under discussion. Human and veterinary medicine were essentially one; this union was best seen in the domain of tropical medicine in which divorce had never taken place and the subjects were historically connected. He recalled the fact that in the very room in which he was speaking 25 years ago an amazed audience had listened to Manson's announcement of the discoveries of Ross in elucidating the mysteries of malaria. What had been his subject? Sparrows, mosquitoes, and protozoa! From a study of tropical trypanosomiasis sprang a large part of modern chemotherapy. Comparative investigations had also led to the elucidation of helminthology, bubonic plague, and other diseases. Human tropical medical research depended upon the pursuance of the experimental method and a close relation between the veterinarian and the medical man. In all experimental work in these fields a better knowledge of veterinary work would be a great boon to the worker upon human diseases, who often was largely ignorant of the natural ailments of his experimental animals and might be led into error by his ignorance. In tropical medicine he saw the beginnings of a cleavage between the two subjects which was extremely undesirable. It was of course necessary in routine work, but in research human and veterinary studies should combine and should be housed under the same roof. He welcomed the establishment of a section of comparative medicine by the British Medical Association as a forward step.

The Filtrable Viruses.

Dr. ANDREWES said that one of the chief of the current problems in veterinary medicine was that of the filtrable viruses, in this country in reference to distemper and foot-and-mouth disease and in other parts of the world in connexion with rinderpest, African horse sickness, &c. Little could be done in any of these maladies except to demonstrate the presence of the infecting agent and in certain cases to produce some degree of immunity. An advance in any one of these diseases would herald a general advance in our knowledge of the others. Deficiency diseases were of importance in the pig, the dog, and in poultry, but not of noteworthy importance in other animals, least of all in the herbivora. Cattle, sheep, and horses were unlikely to be in conditions which would engender an avitaminosis and experimental efforts to produce this in cattle had failed. Veterinary pathology had the great advantage over medical pathology that the worker could utilise the animal in which the disease naturally occurred in his experiments. Great caution was necessary in applying results obtained with one species to others. This danger was exceedingly well exemplified in drug reactions and vegetable intoxications familiar to veterinarians, and even more so in bacterial infections.

Prof. J. LORRAIN SMITH welcomed the institution of the Section of Comparative Medicine. The application of the experimental method was essential to the solution of any problem in medicine. The first light shed upon cirrhosis of the liver, a disease long wrapped in mystery, was gained from the investigation of a disease of cattle in Africa. As a result of experiments we were to-day able to reproduce all phases of cirrhosis of the liver by the application of tar to the skin of animals. From being a disease enveloped in mystery it was now one which could be produced at will. In like manner arteriosclerosis in animals could be produced by varying their diet. Our modern knowledge of diabetes depended upon an experiment on the dog performed by Minkowski in the 'eighties. By application to the experimental method we were widening our conceptions, which was a greater gain than the mere incidental triumphs of pathology or bacteriology.

Prof. C. H. BROWNING said that in studying disease we should free ourselves of the common notion which regarded animals in the light of a defective man and a substitute for him in experimental investigations. To be approximately accurate it was necessary to comprehend a great deal about the animal's physiology and pathology. We tended to regard medicine too much through the eye of the rabbit! We lightheartedly constructed groups of bacteria from results obtained with the serum of the rabbit, whilst

with another species of animal the same types might not emerge. Too close attention to details of this sort constituted a bar rather than a help to progress.

Coöperation between Medical and Veterinary Professions.

Mr. J. MCALLAN (Veterinary Department, City of Aberdeen) said that coöperation between the medical and veterinary professions was of paramount importance to public health. The services of a veterinarian were essential in order to preserve the public from bad food supplies. The medical officer of health should be the administrative head of the department and the veterinarian under him should have control of meat inspection and the milk-supply. The control of tuberculosis in cattle was a matter for combined work between the two divisions, the veterinarian being responsible for the field work; in this capacity he should supervise the production of a clean milk-supply.

Prof. MATHESON spoke of his work in connexion with the Zoological Society of Scotland, where, for the last 14 years, he had been responsible for post-mortem examinations upon all animals dying at the Zoo. Anthrax was excluded before the examination was proceeded with. Intestinal obstruction was a common finding. Tuberculosis was present in a large number of birds, being found in about 10 per cent. of domestic poultry. With regard to tumours, in the first 12 years of this work he only encountered one tumour, a renal growth in a monkey, but in the last two or three years a few more had been seen; they were not uncommon in domestic animals. Gastric cancer and cancer of the alimentary tract or mouth was rare in the lower animals. Papillary overgrowths, akin to those found in coccidiosis of the liver in rabbits occurred in the galactiferous ducts of cows which were the subjects of mastitis.

Dr. R. A. O'BRIEN said he was much impressed with the value of coöperation between the veterinary and medical sciences. It was necessary that money should be forthcoming to advance research, and here the value of field work gained a more ready appreciation and elicited a quicker response than did the less obviously useful academic research. To prove even minor points in animal experiments the difficulties were great and, as in all biological research, large masses of material were a necessity if results were to be reliable. The score of expense was a heavy one. In field experiments the necessary conditions could only be obtained by the coöperation of owners who were often unwilling to coöperate in the conditions requisite for a properly controlled experiment; their point of view was easy to see. He thought this was largely a matter of education and not insurmountable.

Dr. T. G. NASMYTH (Edinburgh) desired to make a confession of his faith in the present and future of comparative medicine in which he had been engaged since, 55 years ago, he first studied veterinary medicine on the farm as a medical student. Years ago he had made the discovery that horses in coal-mines did not suffer from tetanus, the explanation of which had only been forthcoming much later. The outstanding problem in relation to epidemics and epizoötics was the factor he would label "Z." The organisms and the subject existed side by side—some of us were carriers—and yet only occasionally did epidemics occur. Leprosy, cholera, and typhus had disappeared; yet many of the conditions under which they flourished still remained. He strongly advocated that veterinary colleges should become part of the universities and that research into the therapeutics as well as into causation of animal diseases should be prosecuted in veterinary colleges.

Dr. F. A. E. CREW (Edinburgh) said that it was unnecessary to demand coöperation between the two professions since it was always forthcoming between individuals when the need existed and was lacking only in administrative departments. He agreed that controlled experiments with the human subject were impossible, but, as a believer in the universality of biological processes, he held that these could be adequately carried out with other genera. The object of the present discussion, as he saw it, was to proclaim aloud to those in power, bureaucrats and therefore presumably lacking in knowledge and of doubtful morality, that such coöperation was necessary and that it was for them to provide the necessary facilities and money. He believed that the future evolution of man and of animals was within human control, and that by attention to resistance and natural immunity it might be possible to develop disease-resisting strains.

Mr. POOL referred to the contributions made by bacteriology to our knowledge of animal disease. Mastitis in cattle was an infectious disease, associated with the presence of streptococci, upon which further knowledge was desirable. He made a plea for patience in research work and strongly deprecated the hasty issue of ill-considered reports, under pressure from departments which subsidised research. A little more consideration and maturity would greatly add to the value of many articles.

Mr. T. W. M. CAMERON (London) raised the question of the meaning of comparative medicine. It was not synonymous with the study of diseases which man shared with animals, but a comparison of the results of investigations made over the many fields of medicine. Comparative pathology should be a subject apart and not an appendage of human pathology and bacteriology. It was the study of such processes as the varied appearances due to infection with the tubercle bacillus in different species and the evolution of the hydatid cyst which he understood by comparative pathology.

Prof. M. J. STEWART, Dr. DUNNE, Major G. W. DUNKIN, and Prof. E. GLYNN also contributed to the discussion.

SECTION OF PREVENTIVE MEDICINE.

WEDNESDAY, JULY 20TH.

THIS Section met under the presidency of Prof. P. S. LELEAN (Edinburgh) to discuss

PUBLIC HEALTH ADMINISTRATION.

The main question considered was whether all health administration—e.g., in towns, schools, and factories—should be concentrated in a single department, and whether the immediate control in each executive area should be vested in a single individual.

Dr. A. S. M. MACGREGOR (Glasgow) said that a rigid separation between curative and preventive medicine could no longer be maintained. The size of the unit lay at the root of the problem. Larger local authorities could apply the numerous public health measures, whereas small authorities could not carry out their duties efficiently. The MacLean Committee (1918) had recommended the abolition of the guardians and the Royal Commission on National Health Insurance had recommended the abolition of insurance committees. The insurance scheme should include a competent midwifery system and should be extended to apply to dependents. The Scottish Consultative Council (1920) favoured unification of the local authorities concerned with health and an adequate medical service for every member of the community. The Consultative Council of 1923 recognised the present overlapping and waste and the fact that many administrative units were too small to be efficient, and put forward one health authority for each area as the objective. "Regional administration" had been adopted for electricity and was desirable for many health problems—e.g., non-pulmonary tuberculosis, puerperal fever, ophthalmia neonatorum, and orthopædic schemes. The municipal and Poor-law beds in Glasgow, numbering some 5000, could be used to better advantage if they were under unified control. Again, the remedial measures for school-children which had reached a high level, should obviously be applied to pre-school children. The modern tendency to specialise and have separate clinics for tuberculosis, child welfare, venereal diseases, &c., all added to the complexity. Perhaps centres in whose work the general practitioner would take part would be the ultimate solution. The bringing in of the factory worker into a unified scheme was a difficulty. On the other hand, the

proposed new department for mental health was a mistake.

Prof. E. L. COLLIS (Cardiff) referred to the new Factory Bill and criticised the clause giving the Secretary of State power to transfer control of factories to county councils. The local health authorities could not deal with industrial health and diseases adequately. The factories must supply their own medical services (under supervision) and not have a medical service inflicted on them. He cited the growth of the factory medical service in the United States in support of his contentions.

Prof. F. E. WYNNE (Sheffield) was inclined to agree with Prof. Collis; he favoured the exclusion of factories and ports, but would include everything else under one local health administrative unit. The Commission of 1869 recommended one local and one central unit, but the Ministry had not accomplished the unification intended. School medical departments were still often separate in England. Infant and pre-school records were not passed on and school records were mainly pigeon-holed. There was much overlapping and waste. There should be one record, including the pre-school, school, and factory periods. With a unified medical service would come a better and more general training for the young medical officer.

Dr. J. H. MEIKLE (Edinburgh School Board) said the education and health services in Scotland were quite separate, though sometimes coördinated. The 1919 Memorandum of the Scottish Board of Education recognised the need for coöperation. In Edinburgh there was a happy alliance. Joint clinics had great advantages. He favoured coöperation rather than unification.

A communication from Prof. E. W. HOPE (Liverpool) was read, which referred to the many Government departments which dealt with public health and the "preposterous" proposal to have a separate department for port sanitary work. Dr. Hope went on to refer to the anomaly of the destitution authority dealing with vaccination, to the magnificent Poor-law hospitals, and to the many-sided administration of public health which had been built up in London. His ideal was one chief medical officer for each local health unit, including factories.

Dr. FREDERICK DITTMAR (Scottish Board of Health) regarded coördination as essential. Glasgow had Poor-law hospitals with staffs of consultants. The health authority should take over all treatment of disease. In Aberdeen the medical administration of the Poor-law hospitals had been taken over by the health authority; also the schools. In Stirlingshire the medical officer of health was the administrative head of all these services. Dr. Dittmar thought, however, that the industrial health problems of the factories were so distinctive that they should be dealt with by the factories themselves.

Dr. F. N. KAY MENZIES (London) described the apparent chaos of London's health government, which nevertheless produced good work. There was, however, much overlapping, unnecessary correspondence, friction, and variation in standards. Local conditions in the country varied very much, and the crux of the question was: What is to be the unit? For county boroughs the solution was easy. Each county, he thought, should prepare its unification scheme to suit local conditions and submit it to the Ministry.

Dr. W. F. DEARDEN (Manchester) put the point of view of a factory surgeon. He thought local health authorities should only deal with matters which made factories a nuisance to the surrounding community and that the factories should deal with their own industrial health problems. A committee of employers and employed with a Home Office representative discussed industrial dangers and drew up rules and regulations. No local authority could have on its service all the specialists needed for dealing with the various industries. The work of the certifying factory surgeons had changed and they now had to act as neutral officials in advising about regulations, and in investigating industrial poisoning effects and compensation cases.

Dr. MIDDLETON MARTIN (Gloucestershire) spoke in favour of central and local unification. The establishment of the Ministry of Health had not brought about any central unification. In Gloucestershire the medical officer of health was head and the pre-school records were passed on to the schools. Port sanitation was rather special, as regards unification proposals.

Dr. J. PARLANE KINLOCH (Aberdeen) said that in Aberdeen they were now considering the relation of the municipal and Poor-law hospitals (taken over by the municipality) to the voluntary hospitals and the university. He thought that there was nothing so special about factory medical inspection as to interfere with its being taken over by the local health authority. Orthopædic schemes, for example, were of a far more special nature. He believed, however, that sanitary inspectors needed a higher education to enable them to deal with the environmental hygiene of factories and that their association should take up this matter. The area of the local health unit needed to be sufficiently large.

Dr. DAVID MCKAIL (Glasgow) advocated the employment of part-time medical officers and thought it was essential that all medical officers should have at least three years of the rough-and-tumble of practice in order to get a true idea of home conditions.

Dr. HAROLD SCURFIELD (Folkestone) thought these talks did not advance matters much and that the various districts should make experiments in coöperation with the encouragement of the Ministry. He gave as examples the experiments that were being made in Gloucestershire, Essex, and Cardiff.

Dr. H. S. BEADLES (Romford) recommended the coöption of medical representatives on the health committees.

Dr. E. H. SNELL (Coventry) thought that just as one head was necessary for an army, one head was necessary for the local health unit.

Dr. W. A. LETHEM (Ministry of Health) recommended the Cardiff system as a means of providing a good all-round training for future medical officers of health.

Dr. MACGREGOR, in replying, said that the head clinical posts in each specialty should be better remunerated. He thought there was considerable scope for regional coöperation, approved Dr. Menzies's suggestion about county experiments in coöperation, emphasised the importance of continuity of records, and said that we wanted something more than interchange of information.

THURSDAY, JULY 21ST.

The subject under discussion at the second session was

THE NATION'S FOOD SUPPLY.

The Section was asked to consider the duties of the State in relation to the food supply, in so far as they were concerned with research, instruction of parents, maintenance of supplies, and cooking facilities.

Prof. EDWARD MELLANBY'S opening paper constituted a strong plea for the setting up by the Ministry of Health of a board of nutrition composed largely of experts actively engaged in nutritional research. This board would examine the results of research work conducted for the Medical Research Council, the Board of Agriculture, the Empire Marketing Board, and other bodies by study of the work and personal contact with the investigators; it would advise the Ministry about suitable lines of action, and it would initiate research on practical points to fill up gaps in our knowledge. The Ministry, acting on this board's recommendations, would control the feeding of public institutions and institutions in receipt of grants, publish authoritative statements for the guidance of the public, and set up a department for testing the value and vitamin-content of foods. As regards instruction of parents, the Ministry would see that all teaching organisations, including the press, had authoritative information supplied to them instead of the haphazard amateurish,

and often partisan, statements at present available. As regards maintenance of supplies, the Ministry would increase, for example, the facilities for obtaining desirable foods such as "the protective foods," and discourage the production or importation of less desirable foods, according to the needs of the moment. Fish, for example, was an excellent food, the consumption of which was being reduced at present by faulty methods of distribution and sale. The modern practice of buying cooked foods would necessitate attention to cooking facilities.

In leading up to his main proposal, Prof. Mellanby outlined the facts about the fundamental importance of correct feeding in the promotion of health and resistance to disease as shown by the research of the last few years. Knowledge of dietetics was now much ahead of its application, and the machinery for its dissemination was inadequate. He paid tribute to the Government departments and the Medical Research Council for the good work already done, but much more could be done by the better application of present knowledge. Research was carried out in water-tight departments and there was much overlapping; coördination was urgently needed. The Medical Research Council was hampered by lack of funds. The Empire Marketing Board would provide funds. More research workers were needed. Administrators had not time to keep in touch with the work and needed first-hand knowledge. The claims made by the manufacturers of various foods ought to be controlled. Sound advice from an authoritative source was urgently needed. The State should take a stronger line in promoting and coördinating research, in informing the public, and in controlling food supplies.

Dr. T. EUSTACE HILL (County Durham) considered Prof. Mellanby's address and proposals not a counsel of perfection but eminently reasonable, and he favoured the establishment of a board of nutrition. He thought the personal touch was needed to produce a change in dietetic habits. The health visitor had great opportunities in the home but required better training in the subject. Talks at the centres, too, were better than set lectures. The cheapening of foods and the improvement of facilities for distribution were urgent matters. In one district they had gluts of fish, fruit, and vegetables, which were allowed to rot and in another district, not far away, the same articles were sold at exorbitant prices. Allotments should be encouraged and the holders should be advised about the best vegetables to grow, from the point of view of food values. Coöperative societies might do much to facilitate transport of cheap protective foods. Communal kitchens would be a boon to poor industrial districts. The charges for cooked foods were much too high.

Dr. J. PARLANE KINLOCH took up the cudgels for the national cereal of Scotland and went on to show the inadequacy of our milk consumption. He gave a list of the milk consumed per head in various countries, which showed the United Kingdom at the bottom with a consumption only one-half that of the next lowest. For the immediate present the health visitors could do most to educate in the homes, but when the teachers were better educated in food questions, he hoped for greater results from the schools. He approved of communal laundries, which would give the housewife more time for cooking.

Dr. GERALD LEIGHTON (Scottish Board of Health) declared himself an optimist about the milk-supply and considered it unwise to legislate in advance of public opinion.

Sir GEORGE NEWMAN (Ministry of Health) gave a brief sketch of recent legislation to illustrate the great interest which the Government took in food questions. Diets were improving and the public was interested, as the many articles in the press showed. The knowledge of nutrition had not yet permeated the medical profession. When the doctors understood nutrition, the people would learn. Prof. Mellanby's proposition would receive his most careful consideration.

Dr. MACGREGOR referred to the diversity of opinion among doctors on food questions. He thought the recent experience with the unemployed in Glasgow had shown that the usually accepted minimum of calories needed was an overestimate. He also defended oatmeal as an article of diet.

Lack of time prevented a general discussion and, possibly owing to the wide scope of the title, Prof. Mellanby's main proposal—the establishment of a board of nutrition—received scant consideration.

Pulmonary Asbestosis.

This new disease was discussed by Dr. W. E. COOKE (Wigan), Sir THOMAS OLIVER, and Prof. STUART MCDONALD (Newcastle-on-Tyne) from the clinical, pathological, and preventive points of view.

Sir THOMAS OLIVER showed that the crushing of the rock, which may contain 50 to 60 per cent. of silica, was done in the country (e.g., Canada) where it was mined or quarried. British workers were therefore less exposed to the harmful influence of the dust. Dr. Cooke had shown in 1924 that in the manufacture of cloth-like structures from asbestos dust was produced, especially in the carding department. A fatal case of asbestosis had been described by Dr. Montague Murray in 1900 in the *Charing Cross Hospital Gazette*. He (Sir Thomas Oliver) had seen cases in Leeds and had visited asbestos factories in America. Asbestos manufacture had been carried on in this country for 30 years and was largely a familial occupation. The rooms in which carding and spinning were done must be well ventilated and kept clear of dust and floating fibre. In a British factory the dustiest process was the hand-beating of the finished mattresses used for covering and protecting the internal machinery of automobiles, and during this process the men should wear masks and there should be open windows at one end and a strong down-draught at the other end of the shed used, which should be separate from the rest of the factory.

Asbestosis resembled silicosis in producing marked shortness of breath, deficient respiratory capacity, and physical debility, followed only at a late stage by the addition of tuberculous infection. He did not doubt that there had already been several deaths in British factories from asbestosis which had been unrecognised and certified as pulmonary tuberculosis. He described the histories of two women (one, 48 years old, who had worked 30 years, the other, 39 years old, who had worked 18 years), neither of whom had tubercle bacilli in their sputum. Both gave up work on account of loss of weight, increasing debility, shortness of breath, and cough. Asbestos would be put to many uses. It was indestructible by fire or acids, and was used for making tiles, ceilings, and cord. The industry would grow and preventive measures must be adopted at once.

Prof. MCDONALD then described the curious foreign bodies found in the lungs post mortem, in addition to the fibres and particles of silica. They resembled minute crustaceans, but investigation appeared to indicate they were neither animal nor vegetable and they might be silica in a colloidal form, from the hydrolysis of the asbestos fibres owing to long-continued retention in a moist, warm situation.

SECTION OF FORENSIC MEDICINE.

THURSDAY, JULY 21ST.

Prof. HARVEY LITTLEJOHN was to have presided over the sessions of this Section, but was prevented from doing so by the illness which led to his death on August 16th. At the first session the chair was taken by Earl RUSSELL and the subject of discussion was

ALCOHOL AND THE MOTORIST.

Dr. GODFREY CARTER (Sheffield) said that Dr. H. W. Southgate and himself had found that alcohol could be detected in the urine in quantities varying with the amount taken and the time that had since

elapsed.[1] Later, E. Mellanby and H. W. Southgate had established a ratio between the alcohol in the blood and in the urine. It had been found that this ratio stood at the figures 1 to 1·34, showing that the renal epithelium had a selective action for alcohol in secretion. A concentration of 300 c.mm. per 100 c.cm. of urine, at the point of maximal concentration, suggested definite intoxication. When a sample of urine had been obtained it should be quickly bottled to prevent alcoholic evaporation, and glycosuria must be excluded in order to prove that no alcoholic fermentation had taken place.

Dr. EMIL BOGEN (California, U.S.A.) described a method of determining the concentration of alcohol in the breath. The patient was asked to blow up a football having a capacity of about two litres. The air while still warm was bubbled at a moderate rate through 5 c.cm. of a hot solution of 33 per cent. N/15 potassium dichromate in 50 per cent. sulphuric acid. The colour changed from reddish yellow to greenish blue, and was then compared with a series of standards previously made up by the addition of known amounts of alcohol (1, 2, 3, 4, and 5 mg.). The entire test took only two to five minutes. This method, together with examination of the urine, had been used in an investigation at the Cincinnati General Hospital of 500 persons suspected of drunkenness. This investigation had well shown the relationship of the concentration of alcohol in the urine to the degree of intoxication. None of the patients with less than 1 mg. of alcohol per c.cm. of urine had been reported as intoxicated, whilst a little more than half of those having from 1 to 2 mg. per c.cm. were so diagnosed clinically. Three-quarters of those having from 2 to 4 mg., and all of those having 4 mg. or more per c.cm. of urine, had been regarded as drunk. The diagnoses had been very conservative since in these cases the physician was called into court to sustain his impressions, and unmistakable clinical evidence was insisted upon. Even more striking was the relationship between the concentration of alcohol in the urine and the different symptoms usually considered indicative of acute alcoholism. The odour of alcohol in the breath was present in less than half of those showing under 1 mg. per c.cm. of urine, in more than three-quarters of those showing from 1 to 3 mg., and in nearly every instance where the urine contained 3 mg. or more of alcohol per c.cm. On the other hand, the dilated pupils and flushed face, so frequently relied upon as evidence, were found in less than one-third of the cases and were particularly noticed in the moderate groups, being replaced by constricted pupils and pallor in a high proportion of patients admitted in coma or stupor. Inability to stand straight without swaying was noted in less than 20 per cent. of patients showing under 2 mg. of alcohol in the urine, but in more than 80 per cent. of the others who were able to stand at all. In no case with 3 mg. or more was the subject able to stand without swaying. Marked incoördination of the hands was most frequently found in those who had more than 2 mg. per c.cm. Disturbance of behaviour, on the other hand, including garrulousness, volubility, euphoria, boisterousness or pugnacity, were more pronounced in those showing from 2 to 4 mg., for above that they tended to lapse into sluggishness, stupor, or coma.

The estimation of alcohol in the breath, said Dr. Bogen, was the quickest and easiest test yet suggested. As soon as the disturbing factor of the alcoholic liquor still in the mouth and lip was removed (about ten minutes) the concentration of alcohol in the breath approached a fairly constant relationship to that in the blood, since alcohol passed through the lungs very easily. Under 15 per cent. of patients having less than 1 mg. of alcohol in the sample of breath taken were found to be intoxicated, as compared with 70 per cent. of those having from 1 to 3 mg. and 100 per cent. of those having 3 mg. or more. The study of these results and those of other observers indicated that estimation of alcoholic concentration in the urine, breath, and tissues, was the most important single factor in arriving at a correct conclusion as to the degree of a patient's intoxication.

Prof. J. T. J. MORRISON (Birmingham) thought that the actual tests of urine and breath would not be used generally, because it was difficult to get satisfactory specimens and prompt analysis. The fact that renal conditions and disease in general might affect these excretions was not to be overlooked, and the wishes of the accused person had to be considered before the tests were made. The effects arising from the consumption of the same quantity and concentration of alcohol in different persons and also in the same person might vary greatly—e.g., with the amount of food in the stomach and the dilution and the rate of consumption of the alcohol. Many systems of the body were affected by drink, and there was no single effect that might not be present in trauma or disease. The crucial point was, he thought, how much disturbance there was, and no single test would suffice. All possible signs and symptoms must be taken into account.

Prof. ANDREW ALLISON (Glasgow) said that the object of a medical witness was not to give his own impression of a drunken man, but to present to the court a picture of the case as a whole when first seen. The object of the judge was to ascertain as to whether the defendant's efficiency had been so diminished as to render him culpable. Dilated pupils and infused conjunctivæ were inadequate tests for drunkenness. If a prisoner denied drunkenness he should be put in a cell; if he fell asleep within a quarter of an hour he was probably drunk and not suffering from nervousness or shock. Prof. Allison insisted on the necessity of gaining the prisoner's assent before examination, otherwise he might give evidence against himself. In cases of homicide the accused must be warned and the object of such examinations must be explained to him. Also it was wise to consult an independent doctor.

Lord RUSSELL said that if a man was in custody he might be examined without necessarily being warned. The accused should always have the option of calling in his own doctor.

Prof. J. E. W. MACFALL (Liverpool) emphasised the necessity for a lengthy exhaustive examination in every case of suspected drunkenness and for concrete facts rather than ideas. It was important to ascertain when the prisoner thought he had been arrested—i.e., to get his idea of the interval between the time of his arrest and the time of the present examination. It was important that the tests should bear a relation to the actual work which the accused was carrying on at the time. The doctor might drive in a car, for instance, with the drunken man.

In the course of his reply Dr. CARTER said that a man was not fit to be in charge of a car if there were more than 260 mg. of alcohol in 100 c.cm of his urine.

At the second session of the Section Sir WALTER SCHRÖDER (London) took the chair, and the subject of discussion was

The Teaching of Forensic Medicine.

Prof. JOHN GLAISTER (Edinburgh) said that there was a great difference in value between the lectures given by a teacher in constant and immediate touch with the practical side of the subject and the lectures of one whose knowledge was chiefly theoretical. The teacher's field of work should provide material for instruction, such as photographs of cases, whilst the formation of a class museum of illustrative specimens was a valuable adjunct. The visit of a student to a Court of Law during a trial was worth much, as it enabled him to see the surroundings and to hear witnesses examined and cross-examined. Such opportunities commonly occurred during the progress of a teaching term and the courts were willing to give students facilities for being present.

Prof. MACFALL agreed that the teaching of forensic medicine must be correlated with actual cases. The

[1] Brit. Med. Jour., 1926, i., 463; see THE LANCET, 1926, i., 207.

teacher ought to have the confidence of the local coroner and for his expert knowledge to be available at any time. It was difficult to see at what period of the student's career examinations in forensic medicine should take place. A good knowledge of medicine was necessary as a basis, and therefore probably the best time was either just before or after the final examination.

Prof. SYDNEY SMITH (Cairo) said that in forensic medicine the training of the student was less important than the training of the medical practitioner. It was necessary to have a definite course in the subject analogous to that for the Diploma in Public Health. Such work must be done regularly, and therefore it was better to have centres set aside for the work, equipped with the necessary laboratory material. In Egypt every case of violence and the like required complete investigation. In this country this investigation was not done, often because of the question of fees. If there were centres employing full-time staffs this would not arise in the same way. In Egypt every doctor carried a sterile bottle and in cases of poisoning specimens were immediately sent to the laboratories. This system had greatly reduced expenditure.

Prof. ALLISON thought it desirable to have teaching centres well equipped, and if possible to send all cases of poisoning, for instance, to such institutions. There should be more opportunities for discussing the subject, such as those offered by the Medico-Legal Society in London. No such society existed at present in Scotland.

Dr. J. A. KERR (Edinburgh) said that just as a diploma was required for service in the public health department, so there ought to be a similar qualification distinguishing experts in forensic medicine.

Prof. MORRISON pointed out that coroners were handicapped by the town councils in their efforts to emancipate the teaching of forensic medicine. In fatal cases of irritant and corrosive poisons the general practitioner sent quite inadequate specimens of the organs and fluids to be examined. It was deplorable that the teaching of this subject should have been pushed so far into the background, but unless more interest and sympathy was taken by the authorities it was impossible to progress.

Dr. HICKS said that there was no definite procedure laid down as to the proper course to take in poison cases. Any practitioner might be in a position which required such knowledge. He had had painful experience of the difficulties and delay in getting specimens examined and of the decisions as to procedure in these medico-legal cases.

Lord RUSSELL was glad that the general opinion was that much of this work should be post-graduate. The medical curriculum was already overloaded.

Sir WALTER SCHRÖDER thought that something more should be done to bring about a system of forensic medicine which could be brought to bear on general practitioners, and especially those who had to give medical evidence; therefore it was necessary for the teaching to be real and practical. It seemed apparent that forensic medicine should be in part a post-graduate study, but exactly when the instruction should be given, and who should give it, was a problem yet to be solved. He had supported the suggestion that there should be a central post-mortem mortuary in London and the principle involved ought to be extended to the teaching of forensic medicine generally. The question as to who should be entitled to make post-mortem examinations raised difficulties, but the appropriation of the work to a police divisional surgeon might be the best solution, though it would be necessary for him to be in close touch with pathological work. It was a matter for the British Medical Association to decide whether a post-graduate course in forensic medicine should be introduced with a special diploma as a necessary qualification of a police surgeon.

Reviews and Notices of Books.

COMPARATIVE PHYSIOLOGY OF THE HEART.

By A. J. CLARK, *M.C.*, M.D., Professor of Materia Medica in the University of Edinburgh. Cambridge University Press. 1927. Pp. 157. 8*s.* 6*d.*

IN this the first of the series of Cambridge Monographs on Comparative Physiology to be edited by Prof. Joseph Barcroft and Mr. J. T. Saunders, Prof. A. J. Clark has provided a synopsis of the work of different investigators, which will earn for him the gratitude of many who cannot strictly claim the right to call themselves physiologists.

The opening chapters are devoted to the invertebrate heart and to the consideration of certain physiological properties of cardiac muscle both in cold and in warm-blooded vertebrates. They form a summary of the present state of our knowledge, and are necessarily less absorbing than those later chapters in which the author deals in a more discursive manner with general problems, such as the relation of body-weight to heart-weight, to circulation volume, and to the work of the heart in birds and mammals. He shows that the heart-rate in different species tends to vary with the metabolic rate, and since in the larger animals metabolism is much slower than in the smaller ones, the demand of the tissues for oxygen can be met by a slower heart-rate. Prof. Clark points out, however, that this is only true within certain limits; 1000 and 40 beats per minute appear to be the extremes beyond which it is uneconomical to go. Consequently the largest living mammal, the elephant, has to be content with a heart-rate which is no slower than that of its less bulky contemporaries. Considering the valuable services which the tortoise has rendered to cardiac physiology, it seems almost a pity that in the present version of the story the hare should be set to race the rabbit instead of his traditional opponent. The heart-weight in the hare is three times, and the resting pulse-rate is one-third of that in the rabbit. In case of emergency the maximal rates attainable in the two animals are similar; the reserve of the hare therefore compares very favourably with that of his lower-powered connexion.

As a book of reference this will be of real value to those who wish to study more deeply the many fascinating aspects of the subject on which Prof. Clark touches, and there can be no doubt that the author will succeed in his object of stimulating research in comparative physiology.

PYELOSCOPY.

La Pyeloscopie. By F. LEGUEU, Professor of the Urological Clinic and Surgeon to the Necker Hospital, Member of the Académie de Médecine; BERNARD FEY, Head of the Urological Clinic of the Faculté de Médecine; and PIERRE TRUCHOT, Head of the Radiological Department of the Clinic at the Necker Hospital. Paris: Norbert Maloine. 1927. Pp. 114.

Prof. Legueu and his collaborators are to be congratulated in having achieved a fresh advance in the methods of urological diagnosis. These workers, feeling that pyelography was not the last word in the radiological examination of the hollow part of the urinary tract, set themselves to improve upon it, and, during the past four years, they have performed what they term pyeloscopy in a thousand cases at the Necker Hospital. Pyeloscopy, as they define it, is pyelography performed by direct vision with the aid of the X ray screen, and is superior to a simple pyelogram in the same way as screening of the stomach after a barium feed is superior to mere photography on a single plate. It demonstrates the motility and tone of the organs as well as their outline, and brings our knowledge of the working of the excretory apparatus of the kidneys into line with

that of the other hollow organs of the body. The outcome is the book under review.

After a chapter on technique, in which the authors claim that the investigation should be a painless one, they proceed to give a full account of their observations of the normal renal pelvis when filled with a suitable opaque solution. Their description of its behaviour, the method of evacuation, and the action of its sphincters makes fascinating reading, and is freely illustrated by plates taken at different moments during the course of the examination. This is followed by a study of the modifications induced by infective and other pathological changes which may cause delay, hyperactivity, partial or complete retention, or retention with spasm. Finally, the experience thus gained has been brought to bear on a series of cases of well-defined diseases, and with profit. In certain of the conditions examined the writers admit that pyeloscopy has not helped them, but in others, notably early hydronephrosis, movable kidney and the primarily infective lesions, it has proved most valuable in showing just where the fault lay and thereby indicating the most hopeful line of treatment.

This is good work and the account of it is well given. If any criticism of the book can be made it is that the translations of notes in several languages accompanying the plates do not come up to the standard of the rest of the production.

BLOOD CHEMISTRY.

The Clinical Interpretation of Blood Chemistry. By ROBERT A. KILDUFFE, M.D., Director of Laboratories, Atlantic City Hospital. Philadelphia: Lea and Ferbiger. 1927. Pp. 186. $ 2.50.

THIS little book sets out to aid the practitioner by telling him what he can and cannot deduce from various chemical analyses of the blood. The aim is admirable, and many of the sections well done. Those dealing with nitrogenous constituents are especially good; blood-sugar is also fully dismissed, special sections being devoted to the interpretation of glucose tolerance tests. Chapter XII., on blood chlorides, seems either too brief or too long. The truth is that nothing definite can be learnt from figures about chlorides at present, and it would have been wise to tell the reader so frankly. The chapters dealing with dietetic management of metabolic conditions in the treatment of diabetes appear irrelevant, especially when the book omits all reference to such important and relevant subjects as the significance of bilirubin and its derivatives in the blood. There are, however, few serious omissions, and as an introduction to a subject of growing importance to practitioners the book has real merit.

THE GALL-BLADDER.

La Vésicule Biliaire. By M. CHIRAY, Professor agrégé à la Faculté de Médecine de Paris; and I. PAVEL, Assistant Universitaire à la Faculté de Médecine de Bucarest. Paris: Masson et Cie. 1927. Pp. 568. Fr. 70.

THIS volume has the character of those classical works which have made French medical literature famous. Clearly and logically written, it deals with its subject matter in exhaustive, but never tiresome fashion. It is up to date and well documented, each chapter being supplied with a selected bibliography, and we note with pleasure that this list of references is, broadly, international, and thus is free from one of the grave faults of many modern works published in Paris. Cholecystography is fully described, and a series of good reproductions illustrate the radiographic appearances of the diseased gall-bladder. The main criticism to be made of an otherwise excellent volume is that the authors appear to consider "non-surgical drainage" as the one alternative to operative treatment. They advocate this method even in addition to surgery, a prospect which to many will appear superfluous and alarming.

ALLERGY AND ANAPHYLAXIS.

Allergy, Asthma, Hay Fever, Urticaria and Allied Manifestations of Reaction. Second edition. By WILLIAM W. DUKE, Ph.B., M.D., Kansas City, Missouri. London: Henry Kimpton. 1927. Pp. 344. 25*s*.

THERE is in this book an excellent account of the theory of allergy and experimental anaphylaxis, which is dealt with on historical lines. The author disclaims any first-hand knowledge of this part of the subject; but he has made a really useful compilation. He gives a full description of plants that produce pollen, with pictures of those particularly found round Kansas, Missouri, and microphotographs of the various pollens. Other causes of allergy are considered, and also the causes contributory to the reaction. Among these is to be noted the statement that "many asthma cases and many patients with nasal reaction have been made infinitely worse by radical, and even by minor operations in the nose, even operations carried out intelligently by the most careful surgeons." The symptoms of allergy are very fully dealt with. The author describes some convincing cases which show that Ménière's disease, renal colic, and arthritis are occasionally due to allergy. Striking pictures of the various cutaneous reactions are included, and the methods of carrying out the cutaneous and intracutaneous methods of testing are clearly set out. It would have been useful to readers if the process of preparing extracts from various substances, such as dust, had been described; but full references are given. To this second edition the author has added a description of the local passive transfer of hypersensitiveness, and of local desensitisation by treatment of local sensitised areas with the related irritating agent. Unfortunately the description of these complex methods is too brief to be really intelligible. The treatment by ephedrine is also described.

In Part II. a much needed summary of the reactions caused specifically by reagents such as heat, light, cold, and chemical irritants is given. There is an excellent bibliography. The author describes vesicles on the skin produced by protein testing as "hives." It would be advisable in a future edition to add a definition of this uncommon expression.

CAUSE AND CURE OF SPEECH DISORDERS.

By JAMES SONNETT GREENE, M.D., Director, and EMILIE J. WELLS, B.A., Supervisor, of the New York National Hospital for Speech Disorders. New York: The Macmillan Company. 1927. Pp. 458. 20*s*.

THIS book is divided into three main parts dealing respectively with stuttering, stammering, and vocal defects. A variety of subjects are included in the last section, such as intensity, pitch, and intonation, and the attention given to pronunciation should be useful to many people who do not suffer from speech-defects as ordinarily understood. A sympathetic account of the emotional make-up of the stutterer takes up a large part of the book, but little is said about the details of his treatment. The section on stammering is less satisfactory; indeed, the authors do not succeed in giving a clear definition of what they include in this term. They appear to mean any defective enunciation due to physical causes, and they give a list of such causes which includes idiocy, progressive muscular atrophy, bulbar paralysis, Bell's palsy, insanity, cleft palate, and acquired malformations of the mouth, teeth, and larynx. It is, of course, impossible to formulate methods of treatment for speech-defects due to many of these diseases, and in some treatment of the speech would be impossible or undesirable. It would have been better if details had been given as to how the admirable series of exercises described should be applied to special forms of defect, such as cleft palate after operation.

IMMUNITY IN INVERTEBRATES.

L'infection microbienne et l'immunité chez la mite des abeilles Galleria mellonella. By S. MÉTALNIKOV. Paris: Masson et Cie. 1927. With 22 text figures. Pp. 140. Fr.18.

Galleria is a moth whose larva feeds on the wax of the comb in bees' nests; it can be easily reared in the laboratory and evidently forms a convenient object for a variety of experiments in a field which so greatly needs further inquiry—immunity in invertebrates. M. Métalnikov describes some interesting observations on the peculiar nutrition of the animal, but more notice will probably be taken of his experiments on infection and resistance. The animal is highly susceptible to some bacteria (e.g., *B. coli* and *B. pyocyaneus*), moderately susceptible to others (e.g., typhoid, staphylococci), and immune to a number of human pathogens (e.g., tubercle, diphtheria, tetanus). It can be protected by killed vaccines. Immunity, as we know it, is mainly a late evolutionary development in warm-blooded animals, especially in respect of the antigen-antibody reaction. In lower organisms mass immunity by selection of resistant races, and individual immunity by phagocytosis, are more prominent. And it is of the greatest interest to work out the beginnings of the phenomena which we see in mammals and birds: similar work on other lower animals is much needed if any real science of comparative pathology is to be achieved.

SOME FAMOUS MEDICAL TRIALS.

By LEONARD A. PARRY, M.D., F.R.C.S. London: J. and A. Churchill. 1927. Pp. 326. 10*s*. 6*d*.

IF all the crimes in which medical men have been implicated were to be recorded, we fear that a library rather than a volume would be required. At any rate, this would be so if all ages and all countries were drawn upon for the purpose. In the volume before us Dr. Parry has not confined himself to our epoch or to any one country, but has made wise selections from international records. He has compiled an interesting book, in which will be found murders, with doctors as villains and as victims, trials of physicians and surgeons for treason, theft and forgery, and stories of quackery ending in the law courts. Dr. Parry writes well, and spares us the tiresome details which rob so many modern records of all interest.

HANDBOOK OF SKIN AND VENEREAL DISEASES.

Praktikum der Haut- und Geschlechtskrankheiten. Fifth edition. By Dr. MORITZ OPPENHEIM, Professor of Dermatology and Syphilis in the University, Vienna. Leipzig and Vienna: F. Deuticke. 1927. With 55 illustrations. Pp. 284. M.12.

THE rapid progress of our knowledge in the branches of medicine with which this handbook deals has necessitated the appearance of a fifth edition after only three years. This is the modest remark of the author, who in his latest preface instances particularly the new fields opened up by helio- and radio-therapy, the advances in the diagnosis of tuberculous skin affections, and the modern developments in connexion with the examination of the cerebro-spinal fluid in all stages of syphilis. He admits the desirability of an ætiological classification, but thinks the time is not yet ripe for the purpose. The book therefore retains its original arrangement, and departs but little from the classical tenets of the Hebra school. It makes no appeal on the score of its illustrations, which are limited to half-tone reproductions of typical microscopic sections, and woodcuts of apparatus used in the treatment of gonorrhœa. The inclusion of this large subject in the 284 pages of text has resulted in a curtailment of all the dermatological descriptions, and it seems unlikely that without a thorough clinical training either the student or the practitioner could derive much profit from a study of the contents. We imagine that Prof. Oppenheim had his own well-instructed students in mind when he wrote the book, and of these there must be many both on the continent and in this country who have a lively recollection of his vivid demonstrations and lectures. To such and other graduates in the Hebra school this work is confidently recommended. The descriptions are accurate and concise, while the therapeutic sections are entirely up to date and reliable. These points are particularly well brought out in the treatment of syphilis, though it is doubtful if all authorities would agree that bismuth is more toxic than mercury.

SUNSHINE AND HEALTH.

By RONALD CAMPBELL MACFIE, M.A., M.B., C.M., LL.D. London: Williams and Norgate, Ltd. 1927. Pp. 256. 2*s*.

IN this little book there is really not much about sunshine in its relation to health. What there is strikes us as being so good that we regret that the author should have taken up nearly two-thirds of the book with a popularly written account of the physics of radiation, combined with dissertations of a highly speculative nature upon the why and wherefore of this universe. On p. 62, for example, he says: "Let us turn for a moment to the philosophy and religion of radiation," which subject is hardly relevant to a discussion of the effects of sunlight upon health. Dr. MacFie's wide reading, of which his book supplies ample evidence, should have prevented him from referring to the electron as flashing along at the rate of 1,000,000 miles a second, but mistakes of this sort are very few. We hope that the balance of the subject will be restored in a future edition.

EXAMINATION OF CHILDREN.

Clinical and Laboratory Methods. Second edition. By ABRAHAM LEVINSON, M.D., Northwestern University, Chicago. London: Henry Kimpton. 1927. Pp. 192. 15*s*.

THE first edition of this book was founded on a course of lectures, delivered by Dr. Levinson to students at Chicago University, on the interpretation of clinical and laboratory tests in pediatric practice. The success of the former edition has led to the preparation of a second, in which various additions have been made to the account of physical examination and the descriptions of laboratory tests. Among the latter are included many which have no special application to pediatrics, as, for instance, Lange's gold test. The text is accompanied by numerous illustrations both of physical abnormalities and of apparatus, and the book fulfils its objects.

DEVELOPMENT OF THE HUMAN FŒTUS.

Die Entwicklung des Menschen vor der Geburt. By Prof. Dr. Med. IVAR BROMAN, of Lund University. Munchen: J. F. Bergmann. 1927. Pp. 357. M. 24.

THIS book, by the well-known director of the Anatomical Institute at Lund, is in large part a record of his own work in the domain of human embryology. It is thus an authoritative guide for those who wish to make acquaintance with the subject, although in one brief volume only short accounts of each system can be given. It is an excellent descriptive presentment of what one may term the accepted German academic views. These differ in certain particulars from those perhaps generally held in England, but the differences are not very important. The text has not escaped from those errors which seem to persist in embryological works, more especially in the figures. For instance, the illustrations in the section dealing with development of the heart in this book are borrowed. The inaccuracies of the figures of G. Born are reproduced, although their more manifest absurdities have been remedied by omission of the labels. A most misleading figure from Kollmann follows: leaving on one side the obviously ridiculous

description (correctly copied from the hand atlas) of the parent specimen as one of 7·5 mm., the conditions shown in the drawing are so erroneous in many small details that it cannot fail to give a false notion to the reader who has no practical acquaintance with the subject. The figures in this section do not exemplify the text, which is correct, if brief. It is to be regretted that these few illustrations mar the series, for most of the figures in this book are excellent, and often beautiful. Moreover, many conditions are illustrated which are not, we believe, so treated in any English text-book. The descriptive portion of the work is concise, clear, and good, and the whole production leaves a very pleasant impression upon the reader.

LES MICROBES.

By P. G. CHARPENTIER, Professeur à l'École de Médecine de Dijon, Directeur de l'Institut d'Hygiène et de Bactériologie. Paris: Les Editions Rieder. 1927. Pp. 77. Fr.16.50.

IT is, we think, a fact that the French lay public are on the whole better informed on medical matters and human physiology than our own. They are more given to the social discussion of such subjects, they learn more in their education at institutions, and they do not regard conversation about their "in'ards" as carrying a vague suggestion of indecency. Here we have a popular but thoroughly scientific account of bacteriology, directed towards satisfying the layman's natural curiosity. It is a pleasant book to read, agreeably written, and the numerous heliotype illustrations, from photographs of M. Pierre Jeantet of the Pasteur Institute, are amongst the best examples of microphotography and its reproduction which we have ever seen.

JOURNALS.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. Vol. LX. London: John Murray. 1927. Pp. 203. 21*s*.—The sixtieth volume of the St. Bartholomew's Hospital Reports is chiefly remarkable for the comprehensive account which it gives of the work being carried out by different members of the staff on the uses of deep X rays and radium. This account is of the nature of a symposium, seven workers summarising the results obtained in their own particular branch of the research. Sir Thomas Horder contributes an introduction, in which he states that he "knows no instance of a single centre producing in so short a time a mass of work of equal value to this." In the first article Dr. Walter M. Levitt traces the history of deep X ray therapy and shows how it has progressed from empiricism towards becoming an exact process founded on scientific data. He does not describe the results which he has actually obtained, but it may be inferred that they give grounds for satisfaction. Dr. Hopwood, professor of physics at the hospital, gives a compressed but excellent account of the physical properties of radium. Pure laboratory investigation is represented by Dr. R. G. Canti, who has worked for some years, in conjunction with the late T. S. P. Strangeways, at the effect of radium upon living tissue cultures. The object of the work has been to discover "the most efficient way of bringing about a lethal action in malignant growths." The problem is one of great technical difficulty, and no final results can be recorded, but it is evident that Dr. Canti has advanced some way.

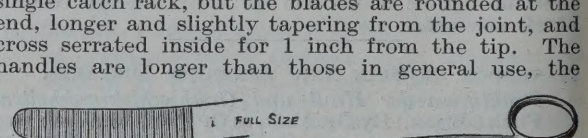
Dr. N. S. Finzi introduces the clinical side of the work with an account of the therapeutic uses of the γ rays of radium, including their observed effects on the different tissues of the body, both normal and abnormal. In his account of the results of treatment hitherto obtained he tries to show that the time has arrived when the practice of treating only inoperable cases of carcinomatous growths should give way to the inclusion of many operable growths. This attitude may be scrutinised in the light of the next three articles by Mr. Geoffrey Keynes, Mr. Malcolm Donaldson, and Mr. Douglas Harmer on the treatment respectively of carcinoma of the breast, cervix, and larynx and tongue. Mr. Keynes describes the results which he had obtained up to the end of the year 1926. Although his statements are guarded, it is clear that a very remarkable degree of success has been obtained. In 9 patients out of 13 with primary carcinoma of the breast the results have been "uniformly good," and the treatment has already been extended to patients with operable growths. Mr. Donaldson has treated carcinoma of the cervix in a much larger number of patients. He claims that radium therapy, as a palliative treatment for inoperable growths, has far greater value than any other method yet devised. Of 20 patients with operable growths, 18 are still alive up to 33 months after treatment. Further time must elapse before results can be assessed. Mr. Harmer opens his article with the statement that the time has arrived when the medical profession must "reconsider the whole question of radium treatment of malignant growths in the upper air passages." His results show that intrinsic carcinoma of the larynx is very susceptible to radium, and that in carcinoma of the tongue also a high percentage of cures can be obtained. They certainly give support to Dr. Finzi's contention as to the treatment of operable growths, and to Sir Thomas Horder's claim that every individual case of carcinoma in these situations should be considered as potential for radio-active treatment *from the first*.

It will be seen that all these clinical articles are interim reports, but they hold great promise for the future. The reports appear to be intended only for those old students of the hospital whose names appear in the list of subscribers. We wish that this volume could have a wide circulation, which its cost (a guinea for a slim volume with few illustrations) may prevent.

New Inventions.

IMPROVED BOZEMANN'S UTERINE FORCEPS.

THIS is a very convenient instrument for packing, or for making applications to the uterus, cervix, or vagina, or for introducing a drainage-tube. The improved forceps have the usual double curve and single catch rack, but the blades are rounded at the end, longer and slightly tapering from the joint, and cross serrated inside for 1 inch from the tip. The handles are longer than those in general use, the



entire instrument is stouter and stronger in construction, and as it is made from stainless steel it is easy to cleanse and sterilise, and is very durable. The round end, which is the size of a No. 5 uterine dilator, greatly minimises risk of perforating the uterus or vagina; the taper admits of its use to some extent as a dilator; its cross serrations provide a ready grip for introducing or removing packing or drainage-tubing, or for holding a pledget of wool when making an application; the greater length facilitates packing a large uterus, and allows the hand to be kept out of the way; the stoutness of the forceps permits twisting when swabbing, painting, or cleansing the cervix. The instrument is useful in conjunction with a Sims's or bivalve speculum, a vulsellum, a gauze roll or ribbon impregnated or not as required, when hæmorrhage calls for quick and firm packing, also for painting or packing the uterus after curetting.

Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, W., are the manufacturers.

J. LYLE CAMERON, M.D. Manitoba,
F.R.C.S. Eng., F.A.C.S.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 24, 1927.

CHANGE OF DOCTOR IN INSURANCE PRACTICE.

THE principle of free choice of doctor is so well accepted in this country that it is regarded as one of the fundamental bases of medical practice, and no doubt it has been a large factor in producing that happy and confidential relation between doctor and patient which is the envy of our continental friends and the despair of those who would introduce a statutory medical service. Nowhere than in the insurance scheme is the principle more firmly established or its carrying out more simple. Persons entitled to medical benefit in England and Wales, amounting to rather more than one-third of the total population, have 14,432 insurance practitioners to choose from. The number who contract out of the scheme to make their own arrangements is trifling, the number of complaints as to the service rendered is a small and diminishing quantity from year to year, and, as the Chief Medical Officer of the Ministry of Health noted in his recent report, the relation is such that the insured person is learning to consult his medical adviser earlier than was formerly the case, owing to the spread of the knowledge of preventive medicine. But free choice has its shady side in insurance practice; and especially during periods of unemployment due to industrial disputes a rigid adherence to the principle may be used by a disgruntled insured person to bring undue pressure upon the practitioner to obtain for him relief to which he is not entitled in equity or by statute. In industrial areas it is well known that the insured person can and does exercise pressure by threatening to transfer, and it has been stated on good authority that for a practitioner to give a certificate of fitness for work is, in some of these districts, a certain prelude to the receipt of notice that the insured person has removed his name from the practitioner's list. There is in such areas a plentiful supply of doctors to select from, competition is keen, and a new man coming in is tempted to go easy with his patients in order to secure their patronage and to build up a list at the expense of his colleagues. It had long been foreseen that some change in procedure was desirable, and certain alterations are to come into force on Oct. 1st. These new regulations are summarised in a notice circulated by the Ministry of Health to clerks of Insurance Committees, which is printed on page 678.

From a study of these regulations it is at once evident that the right of the insured person to choose another practitioner, even when he is already on the list of a doctor practising in his neighbourhood, is not seriously affected, but the procedure for effecting a change is not quite so simple under the new regulations as it was under the old. Formerly the insured person could change his doctor by taking his card across the road to the new doctor and securing his signature to Part B of the card; the acceptance took effect immediately and the insured person could obtain treatment at once. Evidence of the abuse of this right, and of its use in some cases as a lever to extract from the practitioner concessions, such as prescriptions and certificates, is cumulative. At a recent conference of a large friendly society a letter from a doctor's wife was read setting out how her husband was losing his patients by transfer because of his strict supervision of them, and his refusal to keep insured persons on sick benefit after he considered them fit for work. The delegate who read this letter urged the society to suggest some change in the regulations, whereby it should be made difficult for an insured person to effect immediate transfer. Early this year the Insurance Acts Committee of the British Medical Association suggested to the Ministry of Health that the insured person should be required to give at least two weeks' notice to the Insurance Committee of intention to change his doctor, the proposal being justified by the belief that the interposition of a formal check such as this would give the insured person, who may be annoyed because he has been refused a certificate on which he may claim sickness benefit, time to reflect. Thus the new regulations would appear to be the outcome of a demand from two of the principal parties to the insurance scheme—the practitioner on the one hand, and the approved societies on the other. Transfer by consent is not affected, but the insured person cannot in a fit of irritation threaten his doctor that he will go to a more amenable practitioner and secure the certificate to which he thinks he is entitled and which has been refused him.

There will be a wide feeling that the new regulations will help in maintaining the discipline and control which the doctor must necessarily exercise over his patient if his treatment is to be effectual. They should provide an effective check on the unreasonable demands of insured persons, for there is little doubt that many of these are under a mistaken notion as to what they are entitled to under the Insurance Acts. One of the evil effects of social insurance has undoubtedly been to create a feeling that the persons insured are entitled to secure benefits whenever they are so minded. The principle of insurance is not well understood by a large majority of the insured. Further, the competition amongst medical practitioners being what it is, and the difficulty of building up a panel practice being on the increase, it is by no means easy for the practitioner to withstand pressure of this kind. The new regulations should strengthen the hands of insurance practitioners as a whole, and help to restore them to their rightful position. It will be interesting to note what effect they have on the amount of claims for sickness benefit, for it was largely owing to the anxiety of the approved societies on this head that they were drafted. The actual working of the new scheme should not present difficulty. The insured person, on deciding to exercise his right to transfer to another practitioner, is required to obtain an authorisation from the Insurance Committee. This he does by sending his medical card to the Committee with a letter stating his intention to transfer. The medical card will be returned to him with a slip attached authorising the transfer to take effect 14 days after the date of application. This interval enables the first practitioner to continue treatment and prevents the second practitioner from taking over the case immediately except with the consent of the former. The most useful purpose to be served by the interval is, no doubt, the delay which gives the insured person time to reflect and to get over any momentary irritation. The regulations providing for immediate transfer had the effect of reducing the number of complaints

dealt with by the Medical Service Subcommittees, and the new provisions may have a contrary tendency. However this may be, it is certain that the new regulations will make for efficiency.

MEDICAL REPORT BEFORE SUMMARY CONVICTION.

IT is common enough for anyone who sits as a magistrate to find himself called upon to dispose of charges against persons of apparently inadequate mental equipment. There is a right way and a wrong way in these matters. The right way is to remand the accused person for medical report before passing sentence; the wrong way is to pass sentence without the necessary information as to the prisoner's mentality, and then to draw the attention of the prison authorities to his mental condition. The importance of following the correct method would hardly seem to require emphasis; yet it is evident that some benches of magistrates are still at fault; indeed, in one case cited in the last published annual report of the Prison Commissioners (Cmd. 2826), the magistrates actually convicted a prisoner and asked for a report upon his mental condition at the same time.

The typical cases to which the Prison Commissioners refer are instructive. A man is sent to prison for two months for assault and it is remarked that the magistrates confess great doubt as to the prisoner's state of mind, but "as there are no proofs . . . they have no alternative but to send him to gaol." The magistrates ask that the man be kept under observation in prison, and that a report be sent to them upon his release. He is certified insane at the prison, being found to have delusions of persecution and to suffer from auditory hallucinations. In another example quoted by the Prison Commissioners a woman is committed to prison for 14 days for sleeping out, and the magistrates sapiently observe that they send her to gaol "so that there can be an opportunity for mental examination with a view to a report upon her state of mind as she seems to be mentally deficient if not exactly lunatic." Although almost all courts adopt the sensible practice of obtaining a report on the prisoner's mental condition before proceeding to consider sentence, it is strange to find that there are still magistrates who believe in the method of conviction first and mental examination afterwards. The medical officer of Holloway prison makes a further point of some importance. He remarks that the present practice, when a report on a prisoner's mental state is required, is for the Clerk of the Court to stamp on the warrant words to the effect that the magistrates direct that the medical officer should inquire into the prisoner's state of mind. In 98 per cent. of such cases, however, no information whatever accompanies the request. The police, it appears, are always quite willing to give information when asked, but it should not be necessary for the medical officer to ask them. Whenever a mental report is requested, the court or the police should furnish the medical officer with all possible details of the history of the case; in any event, there should be a statement of the reason why the court asks for mental examination of the accused prisoner. The medical officer of Holloway prison is clearly right in maintaining that he is entitled in these cases to be given such information as any medical practitioner would receive when consulted about a patient.

It may be recalled that the question of investigating the mental condition of persons charged with offences was one of the matters discussed at the International Penitentiary Congress held in London two years ago. The Congress asked itself, among other problems, "What may be done to forward the judicious application of the principle of individualisation of punishment by the judge who assigns the penalty to be inflicted on the offender?" Its answer took the form of a lengthy resolution declaring that the judge should first inform himself of all the material circumstances affecting the character, antecedents, conduct and mode of life of the offender, and *inter alia* should have a full knowledge of the physical and psychic conditions and the social life of the accused, and the motives for the crime. Inquiries should be made for this purpose before the trial; penal law should give the judge the power of obtaining information from anyone who knows anything about the defendant's personality and social environment, and if these means give no sufficient idea of his physical and psychic condition, the judge should be allowed to have him examined by physicians and psychologists. While the traditions and practice of British courts of justice have little to learn from the rather vague generalisations of international congresses, the principle embodied in this particular resolution is incontestably sound. It requires to be qualified by the reflection that nine-tenths of the offences annually dealt with by the courts of this country are minor matters (usually met by fines) in which exhaustive personal investigation is neither essential nor indeed always practicable. In more serious charges, where punishment is likely to take the form of deprivation of liberty, full knowledge of the offender's personal and social history and present condition should always be obtained. Anyone who has visited a court of assize or of quarter sessions in England will be aware that our judges seldom fail to insist that such information should be forthcoming.

OPENING OF THE MEDICAL SCHOOLS.

THE following arrangements are announced by medical schools in London:—

Charing Cross Hospital.—Prizes will be distributed at the hospital on Oct. 5th at 3.30 P.M. The annual dinner will take place on the same day at the Hotel Victoria, Northumberland-avenue, at 7 for 7.30 P.M. Dr. Cuthbert Lockyer in the chair.

Guy's Hospital.—The opening address will be delivered at the Medical School on Thursday, Oct. 6th, at 3 P.M., by Mr. M. F. Hopson, who will afterwards present the prizes. The biennial dinner will be held on Friday, Nov. 4th.

King's College Hospital.—The introductory address will be delivered by Sir Berkeley Moynihan at 2.30 P.M. on Friday, Sept. 30th. The annual dinner of past and present students will be held at 7 for 7.30 P.M. on the same day at the Criterion Restaurant, Piccadilly. Dr. G. F. Still will preside.

London Hospital.—The Old Students' Dinner will be held at the Trocadero Restaurant, Piccadilly Circus, London, on Thursday, Oct. 20th at 7.30 for 8 P.M. Dr. Angus Kennedy will take the chair.

London (R.F.H.) School of Medicine for Women.—The introductory address will be given at the School on Monday, Oct. 3rd, at 3.30 P.M., by Mr. R. G. Hogarth.

St. Bartholomew's Hospital.—The Old Students' Annual Dinner will be held on Monday, Oct. 3rd, at 7 for 7.30 P.M., in the Great Hall of the Hospital. Dr. Morley Fletcher will take the chair.

St. George's Hospital. — Sir Humphry Rolleston will deliver the introductory address in the board room of the hospital at 3 P.M. on Saturday, Oct. 1st, and will preside at the Medical School Dinner to be held at the Hyde Park Hotel, at 7.15 for 7.45 P.M. on the same day.

St. Mary's Hospital.—The annual dinner of past and present students will be held at the Connaught Rooms, Great Queen-street, on Saturday, Oct. 1st, at 7 P.M.

St. Thomas's Hospital.—The annual dinner of old students will be held on Friday, Oct. 28th, at 7.30 for 8 P.M., at the hospital. Sir Charles Ballance will preside.

Middlesex Hospital Medical School.—The introductory address will be delivered on Tuesday, Oct. 4th, at 3 P.M., at the Queen's Hall by Mr. Victor Bonney, after which prizes will be distributed by Sir Charles Sargant, Lord Justice of Appeal.—The annual dinner will be held the same evening at 7 for 7.30 P.M., at the Savoy Hotel (Embankment entrance). Mr. Somerville Hastings will take the chair.

University College Hospital.—The annual dinner of past and present students will be held on Friday, Oct. 14th, at 7 P.M., at the Hotel Cecil. Sir George Blacker will take the chair.

Westminster Hospital Medical School.—The inaugural address will be given in the board room of the hospital on Monday, Oct. 3rd, at 3 P.M., by Dr. E. W. Ainley Walker, Dean of the School of Medicine, University of Oxford.—The annual dinner of past and present students will be held at the Royal Adelaide Gallery, Gatti's Restaurant, Strand, on Saturday, Oct. 1st, at 7 P.M. Dr. de Souza will preside.

Annotations.

"Ne quid nimis."

INTERPRETERS OF NATURE.[1]

Sir George Newman has written an interesting collection of nine essays dealing with the careers of men who are all closely identified with the progress of medicine though for very different reasons. The essays have appeared over a considerable interval of time; they are, some of them, official addresses, and as such have already received publicity, while others have been privately circulated as the occasion of their writing dictated. It has required an author of wide sympathies to find a common denominator in Vesalius and Keats, Sydenham and Pasteur, but Sir George Newman points out rightly that these, with Galileo, Boerhaave, Hunter, William Osler, and Michael Foster (taking the names of the heroes of medicine almost at random) have all been interpreters of what their eyes had seen or their hands had handled, and each in his day and way was a pioneer of medical progress.

The essay celebrating the tercentenary of the birth of Thomas Sydenham, in its blend of eloquence and order, is an excellent example of Sir George Newman's methods; it is also valuable reading as a medical sermon. Sydenham is one of the greatest physicians in British medicine. He was never in the strict sense of the word a medical student, but appears to have been created a bachelor of medicine by an act of patronage just before election to a fellowship at All Souls. At Oxford there were great opportunities for the acquisition of the new Renaissance learning, while Linacre had founded lectureships for teaching the doctrines of Hippocrates and Galen in the University. But to Sydenham all this traditional lore was unsatisfactory; he felt the need of clinical practice, and the urge to apply the philosophical tenets, as he came to appreciate them, to some definite uses. Accordingly, in 1655, the year of his marriage, he started medical practice in Westminster. Three years later he went to Montpellier to obtain his first insight into clinical work, from which it may be concluded that he felt doubtful as to the value of the services which his book-learning had fitted him to render. At Montpellier he acquired by personal observation and through the teachings of one Barbeyrac—evidently good both at practice and exposition—methods of practice founded upon first-hand observation of signs, of symptoms, and of the efficacy of the therapeutical measures which these indicated. Thenceforward reliance upon bedside study and recognition of the power of nature formed the foundations of Sydenham's medical practice, and in his studies of the prevalent fevers of his time he laid the foundation of modern epidemiology. Yet great clinician that he was he failed to keep in touch with the progress of physiology, and in writings dated some years after Harvey's discovery he made no mention of it.

Other essays which will be of interest and value to students of medical history are that dealing with the great Paduan medical school and that tracing the influence of Padua upon Leyden, and of Leyden upon Edinburgh through Boerhaave. The whole volume forms a remarkable illustration of the fact that living medicine has its basis on the observation of Nature.

SERUM TREATMENT OF CEREBRO-SPINAL FEVER.

ANTIMENINGOCOCCAL serum is of undoubted value in the treatment of acute cerebro-spinal fever but connected with its administration there are certain fallacies into which the physician may slip unless he is on his guard. These fallacies are discussed by Dr. Edouard Frommel in a recent issue of the *Schweizerische Medizinische Wochenschrift*, Sept. 3rd, p. 873. It has been shown experimentally, he says, that intrathecal injection of horse serum in a normal man will cause all the signs and symptoms of acute meningitis. In such an attack there is in the early stages a polymorphonuclear leucocytosis and an increase of albumin in the cerebro-spinal fluid; whilst in the later stages the polymorphs are rapidly replaced by lymphocytes. The reaction generally passes off within 48 hours, though fatal cases have been reported. In acute cerebro-spinal fever the symptoms often tend to clear up if serum is given at the onset; the signs and symptoms abate and the cerebro-spinal fluid returns to normal. In these cases the serum reaction is either masked by the real disease or, as Dr. Frommel suggests, the membranes are too badly damaged by the acute infection to react to the serum as they would in a healthy subject. The period of acute inflammation is followed by a period of recovery, during which the inflammation subsides, the cells regain their normal function, and with it their power to react normally to foreign protein. This period is characterised by an increased sensitiveness to serum, especially if it is only given at long intervals. Thus when, after the preliminary injections, serum treatment has been stopped for a time, a further injection may be followed by a recrudescence of all the signs and symptoms of meningitis and an increase of the albumin and cell-count of the spinal fluid. This recrudescence should clear up in a few days if no more serum is given, but failure to recognise its cause may give rise to errors of prognosis and treatment, because the reaction will be mistaken for a relapse of the original disease, and the administration of serum, which is alone responsible for the symptoms, may be continued. These after-effects can be avoided if serum injections, once begun, are continued at regular and fairly frequent intervals (one to three days), until all signs and symptoms have abated and the cerebro-spinal fluid is clear. Once this stage has been reached and serum treatment has been stopped for a time, it should not be started again for an exacerbation of symptoms, unless examination of the cerebro-spinal fluid has made it clear that the relapse is genuine and not merely a delayed reaction to the previous treatment. Certain cases, Dr. Frommel points out, react badly to serum from the very start, and in these it is better to stop its use immediately.

EPHEDRINE.

FOR the last 5000 years the Chinese plant, Ma Huang, has been employed as a medicinal herb in the folk medicine of the East. The plant has been identified botanically as *Ephedra vulgaris* var. *helvetica*, and 40 years ago K. Nagai isolated from it an alkaloid to which he gave the name ephedrine. Ephedra is widely distributed throughout Europe, Asia, and America, but the varieties found in America are stated by C. Nielsen, H. McCausland, and H. C. Spruth to contain no alkaloid. From the European variety of *Ephedra vulgaris* E. Merck obtained a substance isomeric with ephedrine, to which he gave the name pseudo-ephedrine. The empirical formula of these substances is $C_{10}H_{15}ON$, and they are related in structure to adrenalin, tyramine, and phenylethylamine. K. K. Chen and C. F. Schmidt were the first to investigate by experimental methods the action of Ma Huang, and to show that the prolonged rise of blood pressure, the cardiac acceleration, and the vasoconstriction observed as a result of intravenous administration of a decoction of *Ephedra vulgaris* were due to the presence of ephedrine in the crude drug. They showed further that the action of ephedrine on the circulation, on smooth muscle, and on secretion was analogous to that of adrenalin and was due to a stimulation of the neuro-muscular and neuroglandular intermediate substances. While for the most part ephedrine elicits responses similar to those produced by adrenalin, there is one outstanding difference between the two drugs.

[1] Essays. By Sir George Newman, Chief Medical Officer, Ministry of Health. London: Faber and Gwyer, Ltd. Pp. 296. 12*s*. 6*d*.

Ephedrine, being more stable, is effective when given by the mouth. Chen and Schmidt showed that a dose of 60 mg. given in this manner to a man produced a rise in blood pressure amounting to 20–30 mm. Hg in 15–30 minutes, and that this rise persisted for three or more hours. Another difference between the action of the two drugs is also related to the higher stability in solution of ephedrine. Its action is less intense but more prolonged than that of adrenalin. For example, in a comparative study of the physiological actions of ephedrine, tyramine, and adrenalin, Chen and Schmidt found that ephedrine in a dose 500 times as great as that of adrenalin produced a similar rise in blood pressure when given intravenously to anæsthetised dogs, but that the height of the rise was more slowly attained and its duration about seven times longer than the rise produced by adrenalin. The effect of tyramine on the blood pressure of anæsthetised dogs was found to be intermediate, in intensity and duration of response, between that of adrenalin and that of ephedrine. Tyramine, however, in doses of 100 mg. by mouth produced no rise in blood pressure in man, whilst an equimolecular dose of ephedrine raised the systolic and diastolic pressures by 15–20 mm. Hg under these conditions. It seems probable that the increased stability of ephedrine over tyramine, and of tyramine over adrenalin, is related to the number of phenolic hydroxyl groups contained in the molecule, adrenalin possessing two, tyramine one, and ephedrine none. These differences, however, are insufficient to account entirely for the differences in physiological response produced by the three substances. Were this not so, the action of β-phenylethylamine on blood pressure would be as prolonged as that of ephedrine, whereas in point of fact the action is of greater intensity, but of much shorter duration. Moreover, as shown by Chen, β-phenylethylamine, like adrenalin, is inactive when given in doses of 50–150 mg. by mouth to man, and pseudo-ephedrine, which differs from ephedrine merely in the reversal of the stereochemical configuration of the —HCOH group, shows an action similar in type to that of ephedrine on the blood pressure of man and of dogs, but much weaker in intensity. It is clear, then, that the constitution of the side chain of the phenyl ring is an important determining factor in the pharmacological action of these drugs.

A substance having the pharmacological properties of ephedrine should prove of great value clinically in those conditions in which a prolonged adrenalin effect is desired. Its action in man has recently been the object of a series of physiological and clinical investigations. W. S. Middleton and K. K. Chen have studied the objective and subjective effects of its administration by mouth to man, the ophthalmological effects of its local application, and the reactions of asthmatics to the drug. They find that doses varying between 50 and 400 mg. produce an average rise in systolic pressure of 28 mm. Hg, and that this rise is usually accompanied by some quickening of the pulse. The rise in pressure is manifested about 30 minutes after the oral administration of the drug, reaches its maximum in about one and a half hours, and begins to fall about two hours later. The dose recommended by them is from 60–90 mg., and with this amount such untoward symptoms as perspiration, tremor, palpitation, and faintness, sometimes observed with the larger doses, were absent. They have also been able to confirm the original observation of K. Miura in 1887 on the mydriatic effect of the drug, in that dilatation of the pupil begins about 15–30 minutes after instillation, reaches its maximum in 30–60 minutes, and lasts from 3–9 hours. No signs of conjunctival irritation were observed. Ephedrine has also been shown to be effective in the treatment of spasmodic asthma. Its beneficial action in this condition has been demonstrated by W. Berger and H. Ebster, and according to them it sometimes produces relief in cases of migraine. These investigators have recently made a clinical study of the action of ephetonin, a synthetic substitute for ephedrine. This substance also is active when given by mouth to man, and benefit is stated to have been observed in a large number of mild and moderately severe cases of asthma, in chronic bronchitis, and in hay fever, in which last condition the drug was employed in 5 per cent. solution as a nasal spray. It seems likely that in ephedrine we possess a valuable therapeutic agent, but the extent and limitations of its use can only be determined by more extensive clinical investigation.

GERMAN DERMATOLOGICAL CONGRESS.

THE fifteenth annual congress of the Deutsche Dermatologische Gesellschaft was held at Bonn from Sept. 5th to 7th, and was a notable gathering, both from the scientific and the social point of view. Prof. Erich Hoffmann, of Bonn, whose name will always be associated with that of Schaudinn in the discovery of the spirochæte of syphilis, made an admirable chairman, and was ably seconded by a large staff. The meetings, at which no less than 115 communications were offered for debate, were held in the Beethoven concert hall, and the main features of the programme were papers and discussions on the biological and physical characters and effects of X rays and of the Bucky "borderland" rays which have been on trial in Germany for the past year. Dr. G. Bucky, who now lives in New York, himself took part in the discussion. Among some 400 dermatologists who attended the congress were Prof. P. G. Unna, who was described by the chairman as the Nestor of dermatology, and Profs. Karl Herxheimer (Frankfurt), Josef Jadassohn (Breslau), J. R. Almkvist (Stockholm), Howard Fox (New York), and J. F. Schamberg (Philadelphia). The sessions began daily at 9 A.M. and with a luncheon interval of two hours continued till 6 P.M. On the last afternoon, at Prof. Hoffmann's clinic, there was a demonstration of many rare and interesting cases, these being afterwards discussed in full conclave in the Beethoven hall. Official but quite informal entertainments were provided every evening, not the least popular of these being a river trip to Remagen by Rhine steamer with fireworks and illumination of the Bonn frontage. Thanks largely to Frau Hoffmann and her lady helpers the meeting added fresh lustre to the reputation for hospitality which the city of Bonn has so long possessed.

POISONING FROM SOLID FUEL.

DURING the war when methylated spirit was difficult to obtain solidified fuel became popular as a substitute. It has certain advantages over a fluid fuel, such as portability, and many people still find it convenient especially for use when travelling. In the September issue of the *Analyst* Sir William Willcox and Mr. C. Ainsworth Mitchell draw attention to the danger of leaving such tablets within the reach of children. They describe a case where serious illness followed the consumption by a boy of 16 of 5 g. of a substance which was designed for use as fuel, and which on examination agreed in its characteristics and reactions with metacetaldehyde. The boy is said to have swallowed a portion of a tablet in mistake for a sweet. No ill-effects occurred till seven hours after when the patient became flushed, restless, and delirious. A few hours later the temperature rose to 100° F. and convulsions occurred, followed by five further attacks of convulsions. The urine had sp. gr. 1·014, was very acid, and contained a trace of albumin. There was marked tenderness of the calves of the legs during this period. The temperature remained between 100° and 101° F. for 36 hours and then fell to 99° F., where it remained for 24 hours, afterwards becoming normal. The treatment consisted in large doses of alkalis (in the form of sodium citrate, 60 gr.; sodium bicarbonate, 30 gr.; water to 1 oz.) given every four hours by the mouth. Rectal injections of 2 drachms of sodium bicarbonate to the pint of normal saline were given every six hours. Throughout the period during which the convulsions

occurred chloral (10 gr.) and potassium bromide (30 gr.) were given four hourly. The urine remained very acid for three days in spite of the large doses of alkali that were administered. After the convulsions had ceased potassium bromide, in doses of 15 gr., was given three times a day for four days. The patient made a good recovery, but the albuminuria persisted for four days. After recovery there was some loss of memory for several days. Sir William Willcox and his collaborator comment on the curious fact that metacetaldehyde should be so much more active than its isomer, since relatively large doses of paracetaldehyde (paraldehyde) can be taken without ill-effects. It is possible, however, that the action may have been due to an impurity.

MUSCULAR EFFORT AND CARDIAC FAILURE.

THE limitation of muscular effort and its relation to cardiac failure was discussed in the July issue of the *Quarterly Journal of Medicine* by A. E. Clark-Kennedy and Trevor Owen. Experiments were performed on healthy young adults to determine the respiratory exchange at increasing rates of work, which was of a very severe nature. The effect of breathing air containing 26 per cent. and 16 per cent. of oxygen, and also a mixture of air and 5 per cent. carbon dioxide, while performing similarly severe work was also determined. It is concluded that the alterations in the respiratory exchange during exercise, when air or other oxygen-nitrogen mixtures are breathed, are chiefly due to lactic acidosis, and when the pressure of carbon dioxide in the inspired air is also increased, a lactic and carbonic acidosis are concerned. The authors maintain that carbon dioxide elimination as well as oxygen supply must be an important factor in determining the amount of work of which a man in capable. An increase of oxygen in the inspired air makes the elimination of carbon dioxide easier, by delaying the accumulation of lactates, the physico-chemical factor in the limitation of voluntary effort being a rise of hydrogen-ion concentration in the blood and tissues. This is ultimately dependent upon failure of the whole cardio-respiratory system, including the heart, lungs and blood, but the output of the heart is sufficient to cope with the venous return, and the circulation does not fail before the ventilation. In heart failure due to disease, there is clinically venous congestion and œdema of the lungs and other tissues. This does not occur in extreme muscular exhaustion in health. It is therefore improbable that the mechanism is the same in both cases—i.e., exhaustion of the reserve power of the heart. In compensated heart disease congestive heart failure does not occur with violent muscular effort, the exercise being compulsorily abandoned before cardio-respiratory disintegration occurs. This could be explained if the ability to effect pulmonary ventilation is reduced in a degree corresponding with the reduction in the heart function, and it has been shown that the vital capacity is diminished in patients with heart disease. This may be due to a protective mechanism, and if this protective reaction fails, congestive heart failure would occur. The article is illustrated by two plates showing the apparatus used and full details are given of the experiments on which this theory of heart failure is based. In the concluding discussion Clark-Kennedy and Owen compare the mechanism of limitation of effort in health with that which is found in congestive heart failure, where not only does circulation fail before ventilation, but the cardiac output no longer keeps pace with the venous return; for, as they point out, the term heart failure is capable of more than one interpretation. To the physiologist it signifies that the heart is no longer able to maintain an adequate blood-supply to the active tissues; oxygen-want, in other words, is their criterion, since all the manifestations of circulatory insufficiency consequent on violent exertion, in the normal healthy individual, can be accounted for by oxygen-want. The clinician, on the other hand, is accustomed to think in terms of the abnormal. He is concerned not with healthy young men, but with those less fortunate persons whose myocardium is already scarred by rheumatic or other infection. The clinician's picture of advanced heart failure is something quite unknown in the realms of physiology; it is that of the patient with orthopnœa, œdema, and venous congestion of the internal organs. These symptoms are manifestations not of oxygen-want, but of the inability of the ventricles to keep pace with the venous inflow. It is with the first of these two conceptions that the writers' experimental observations are concerned. Prof. A. V. Hill and his colleagues have shown that the duration of violent exercise is limited by the oxygen intake. When the oxygen requirements of the tissues are greater than the supply coming from the lungs the body contracts, as they express it, an "oxygen debt." The more violent the exertion the more rapidly does this debt mount up. But like other overdrafts it had its limitations, and the attainment of these limitations spelt the cessation of exercise. Thus the mile runner has to go more slowly than the sprinter or his oxygen debt will stop him before he reaches the tape. Having worked out the limitations of oxygen intake and oxygen debt respectively, Hill was able to calculate the speeds at which it is theoretically possible to run different distances; and he has shown that the times calculated in this way were just a little better than the corresponding actual records established by the world's champion athletes. Clark-Kennedy and Owen now suggest that CO_2 output as well as oxygen intake should be considered in this connexion; and further, that the limitation of voluntary exertion in normal subjects depends on a simultaneous failure of cardiac and pulmonary functions. The latter hypothesis is opposed to that which has hitherto been current—namely, that circulatory insufficiency supervenes while pulmonary ventilation still remains adequate.

MECHANICS OF THE GALL-BLADDER.

THE exact mechanism by which the gall-bladder empties its contents is still unknown. The theory that the flow of bile is regulated by any sphincter-like action at the mouth of the gall-bladder can no longer be maintained, and in view of recent research it is even difficult to find evidence of any active contraction on the part of the muscle of the gall-bladder itself. The introduction of cholecystography by Dr. E. A. Graham has not only led to easier diagnosis in many cases of gall-bladder disease, but is enabling workers in all parts of the world to investigate more closely the physiology of the biliary tract. The work of Dr. Graham himself and of his associates, G. H. Copher and S. Kodama, has suggested that the rôle of the gall-bladder is chiefly passive, its contents being emptied mainly by the washing out of bile when fresh bile flows in, or by the elastic recoil of the distended gall-bladder at the moment when relaxation occurs of Oddi's sphincter at the duodenal termination of the common bile-duct. The chief evidence for this view lies in an ingenious series of experiments in which a small rubber bag was substituted for a gall-bladder in a dog and was shown to fill up with dye and subsequently empty itself in just the same manner as the gall-bladder itself had done. Recent work by G. E. Burget [1] of the University of Chicago goes to support the theory that the gall-bladder itself is incapable of contraction and that its control of the bile flow is confined to the action of a certain tonus which facilitates emptying when the opening into the duodenum becomes patent. An opposite view is set out by A. Hamrick, of the Mayo Foundation, Rochester.[2] He has made numerous studies with the aid of X rays of the movements observed in animals after the injections of iodised oil into the gall-bladder. The opaque oil was

[1] G. E. Burget: Amer. Jour. Physiol., 1927, lxxxi., 422.
[2] R. A. Hamrick: Amer. Jour. Med. Sci., 1927, clxxiv., 168.

introduced directly into the gall-bladder by a simple surgical operation, and X ray photographs taken during the subsequent period demonstrated its progress from the biliary tract into the intestine. In a large series of animals no expulsion of oil or other movement was ever observed during fasting, nor did factors such as increased intra-abdominal pressure appear to have any effect. However, when food was administered—especially food of a fatty nature, such as egg-yolk and cream mixture—the gall-bladder appeared to empty rapidly. Just before or during emptying the shape of the vesicle became elongated and pointed towards the cystic duct, an appearance which was noted so frequently that Hamrick concluded that it must be indicative of some intrinsic contraction of the musculature of the gall-bladder. Emptying did not continue simultaneously with digestion, the meal being expelled from the vesicle at various intervals following the ingestion of food. In another experiment a rubber tube was fixed so that it proceeded from the lower portion of the common duct through Oddi's sphincter in the lumen of the duodenum, keeping the lower end of the duct continuously open. In these circumstances external pressure over the gall-bladder was sufficient to expel some of its contents, but complete emptying was only brought about by feeding. Hamrick considers that the muscle of the gall-bladder itself is the main agent bringing about normal emptying of the organ, but it is hard to discover in his published work sufficient ground for this opinion. It is, on the other hand, abundantly clear, as other observers have insisted, that emptying occurs in relation to movement of the duodenum. The theory of contrary action of Oddi's sphincter and the musculature of the gall-bladder has not found support in recent years, but Hamrick's present work does, perhaps, give grounds for believing that the movements of the bile vesicle are not as entirely passive as has recently been maintained.

CITY HEALTH ADMINISTRATION.

NEITHER the lay public nor the bulk of the medical profession has any clear conception of the variety of duties and responsibilities undertaken by those who enter the public health services. The former visualise the health departments as clearing-houses for complaints about nuisances more or less vaguely affecting the public health; the latter are most familiar with the operations of the epidemic sections of these departments, having as a rule but a hazy idea of the ramifications of their other pursuits and viewing them with a cynical suspicion which is rarely acute enough to promote a closer inquiry. Dr. Carl E. McCombs, of the National Institute of Public Administration and New York Bureau of Municipal Research, has written a book entitled "City Health Administration,"[1] which is designed to enlighten all classes of the American public on the subject; it is written in a lucid and interesting style, and its scope and thoroughness clearly mark it out for the use of those who are preparing for a life of public service, whether official or voluntary, and the lessons which it gives will be useful in all countries.

The book is divided into three parts dealing with (1) Municipal Health Functions; (2) the Organisation and Administration of Sickness Preventive Functions, and (3) the Organisation and Administration of Sickness Treatment Functions. The unattractive character of these headings should not be allowed to repel the prospective reader. Under each of them the existing arrangements in America are described and criticised in a succession of chapters devoted to every aspect of the organised prevention and treatment of disease. On this side of the Atlantic the subject is one of first importance, since the Government's proposals in relation to the administration of the Poor-laws are likely to bring the whole of British public health administration under critical inspection at no distant date. Dr. McCombs, with whose point of view we find ourselves throughout in substantial agreement, will repay careful reading by all who are interested in the municipal side of local government. Young public health officials, too, will find help in the solution of many of the awkward problems of administration with which they are constantly faced.

[1] London and New York: The Macmillan Company. 1927. Pp. 524. 24s.

ALTHOUGH the returns of the general election in the Irish Free State are not complete at the time of writing, a number of medical men have already been elected. In South Dublin, Dr. T. Hennessy was elected on the first count, heading the list of Government successes, while Dr. Myles Keogh, who formerly sat as an Independent but now comes forward as a Government candidate, was also elected in the same constituency. In Co. Cavan, Dr. J. J. O'Reilly, also a Government candidate, was successful. Three medical men have been returned in the Fianna Fail interest—namely, Dr. P. J. O'Dowd in Co. Roscommon, Dr. James Ryan in Co. Wexford, and Dr. F. C. Ward in Co. Monoghan. In addition to these six, Sir James Craig has been returned as an Independent Member for Dublin University.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLII.

THE TREATMENT OF OPEN FRACTURES OF THE LIMBS.

THE main treatment of any open fracture must be (1) to render the wound clean, which entails a thorough excision of all lacerated tissues; (2) to convert it as soon as is possible—i.e., immediately or by secondary suture—into a closed fracture, and (3) to rectify the fracture itself.

Excision.

It may be urged that a complete excision is unnecessary when the wound is caused from within by a sharp fragment which has perhaps momentarily penetrated the skin, creating a small puncture wound, and when the damage to the skin and muscle are slight. The necessity for excision in these cases must depend on individual judgment based on the condition seen; in some cases interference is unnecessary. When there is doubt prejudice should be in favour of excision, since otherwise a definite risk of sepsis is involved. Not only is the virulence of an infective agent an unknown quantity, but the whole point of excision as a routine is to cleanse the wound and so gain the one chance of its successful primary closure. With a few exceptions it is safer to apply the rule of complete excision to all open fractures.

When a large fragment has penetrated the skin from within, or the external injury from without has caused an extensive wound with much laceration of the skin and soft tissues, it may not be possible to close the wound after excision. This is more especially true in wounds on the inner aspect of the leg and the region of the ankle-joint, common sites for such injuries. In such circumstances it is useless to bring the skin together under tension, since sloughing almost invariably follows; in my experience, too, it is a dangerous procedure to undermine the skin in order to close the wound, since in this way an infective agent is given a wider area over which to act. In such cases, therefore, it must be recognised that the severity of the injury to the soft tissues has excluded the possibility of obtaining a completely closed fracture immediately; and though such wounds are usually allowed to heal by granulation, if the chance arises for closure by secondary suture it should be

taken. When in the first instance the wound is left open it is necessary only to cover it. Drainage-tubes, gauze packs, and so forth serve no useful purpose; they are, as a rule, sure paths of infection and should not be introduced.

It may be reasonably urged that if open fractures do not come into a surgeon's hands until a day or two after the accident, when infection has already occurred, it is either not necessary or not justifiable to deal with the wound radically. Again, every case must be judged separately. It may be unnecessary to excise a small wound which has been inflicted 24 or 48 hours previously and is not septic. On the other hand, if infection is present but localised a complete excision is often practicable, and may be extremely useful; but it is problematical whether free excision at this stage will render sterile an already infected wound, and complete closure at any rate should not be attempted. In the civil open fracture it is rare to encounter an acutely spreading infection which demands wide incisions, or even removal of the limb. The essential point is that all open fractures must be treated within the first few hours, and in the majority of cases infection is prevented by excision of the wound within six or up to twelve hours of its causation. As a general rule, the presence of shock need not be a contra-indication to excision and splinting. How far such a course may be negatived by severe shock must be a matter of judgment, and it should be borne in mind that immobilisation of the injured limb in itself tends to reduce shock.

To fulfil the demand of a complete excision it would appear logical that the fractured surfaces or fragments of bone which have been exposed to infection should be removed. In the completely shattered bones caused by gunshot, some surgeons advocated the removal of all completely loose fragments, while others retained all fragments of any size as useful for the eventual repair of the bone, though by doing so sepsis might be prolonged. It has been recommended, too, in civil open fractures that the protruding fragments should be excised. In my practice this procedure has not been adopted, as apart altogether from the inevitable shortening, or risk of non-union, fragments of any size are necessary for the restoration of alignment, and in the lower limb especially are essential for the restoration of the full strength of the bone for purposes of weight bearing. In all cases the very small completely detached fragments of bone are removed together with the shreds of periosteum, and the exposed surfaces of the larger fragments cleansed; in the exceptional case the nature of the accident or intense soiling of the fragments may demand a more extensive removal of bone; in the majority, however, it is justifiable, in my opinion, to preserve all bone fragments.

Restoration of Alignment.

The alignment of the bone should be restored after the excision has been completed. Often it is extremely tempting to fix the fragments in position straightway by a plate or other means, especially as it is a common experience afterwards to find that slipping has occurred from the reduction obtained at the operation. In all probability fixation may be done many times without untoward results, but as a general rule, in my opinion, it should never be done. The main concern at this stage must be to obtain a clean and, if possible, a closed wound, and the alignment, though it should be attended to, for the moment must be a secondary consideration. There is no knowledge of the type of organism that has gained entrance and no guarantee that the excision has been sufficiently complete to prevent sepsis; the risks of infection in every case are too great to permit of the introduction of any foreign body for the purpose of fixation, and the results seen from this are often lamentable.

If it is not possible to maintain alignment by suitable splinting and traction then at a later date (10–14 days), if there is no evidence of sepsis in a closed wound, an open operation may be performed and reduction and fixation effected. This should be done in the full realisation of the fact that sepsis may be lit up immediately, or that a mild infection may occur at a later date; under no circumstance should such an operation be undertaken in the presence of a still open wound. In favour of operation it must be realised that gross displacement, obvious within a week or two of the accident, tends rather to increase than diminish; that in the leg, where this question is most likely to arise, errors of alignment give rise to greater disability than in any other part of the body; that the margin of time in which a perfect result can be obtained is a small one, for if the question is shelved and an operation is decided upon when malunion has occurred, far greater mechanical difficulties present themselves, and the chance of the perfect result is much diminished. With a better understanding, however, of the necessity and requirements of the initial operation and of the more effective methods of splinting, the secondary operations should become increasingly unnecessary.

The Value of Complete Immobilisation.

The maintenance of absolute rest of the part wounded must be achieved by the splinting. The value of a complete immobilisation of a limb in these cases cannot be over-estimated; if it is essential to assist in the healing of a wound that has been closed by operation, it is even more essential for the wound that has become infected. Immobilisation is best obtained in both the upper and lower limbs by means of a Thomas splint with traction, which must be suited to the position of the wound; it should be continued until the wound has healed or sepsis has quietened, when, if the alignment is satisfactory, provision may be made to permit of voluntary movements of the joints. Occasionally, in the lower limb more especially, the mobility of joints may have to be sacrificed temporarily, at any rate, in order to obtain stability of the bone.

In my own experience union is delayed more frequently after an open fracture than in any other type, not including the cases in which there has been an obvious infection. Even in the best circumstances, when the wound has been excised and closed, alignment restored, the limb appropriately splinted, and any obvious signs of inflammation are absent, union may be delayed for a considerable time. It is my impression, founded on the condition found at secondary operations, that it is the presence of a septic infection which prevents union, though it is of so mild a degree that there has been no obvious evidence of it in the wound or in general systemic disturbance. In the large majority of such cases union does eventually become firm, though to achieve this immobilisation at the site of fracture may have to be considerably prolonged. If, therefore, the alignment of the fragments is satisfactory, a secondary operation should not be undertaken for delayed union in these cases; operative measures will tend to maintain or exaggerate the sepsis, however mild, and thus defeat their own object.

F. D. SANER, F.R.C.S. Eng.,
Surgeon to (and Surgeon in Charge Fracture Department) Royal Northern Hospital, London, N.

PRINCE OF WALES'S HOSPITAL, TOTTENHAM.—Towards £50,000 appealed for on behalf of the Prince of Wales's Hospital, Tottenham, Sir Albert Barratt, one of the governors, promised £10,000 on condition that the hospital raises a like amount. This has now been done and the donation has accordingly been claimed.

CHARING CROSS HOSPITAL.—The income of Charing Cross Hospital last year was £56,272 and the expenditure £54,810, thus leaving a balance of income over expenditure of £1462. The hospital having acquired the adjacent premises, formerly occupied by the Royal Westminster Ophthalmic Hospital, which has been removed elsewhere, will utilise them for some of the present needs. The sum of £70,000 had to be paid for the freehold and buildings and £30,000 will be required for alterations and equipment. The hospital is out of debt.

THE UNIVERSITY OF LONDON: ITS PRESENT CONSTITUTION AND MACHINERY.

BY PERCY M. WALLACE, M.A. OXF.,

I.*

BY the promulgation on February 13th, 1900, of the Statutes made by the Commissioners appointed by the University of London Act, 1898, followed a fortnight later by detailed Regulations supplementary thereto, those responsible for the administration of the University, together with a large number of institutions and individual men and women intimately concerned with the subject-matter of these documents, found their long suspense at an end. At last they knew where they stood—or rather where they would stand as soon as these Statutes and Regulations came into active operation. On the whole the prevailing sentiment was one of relief. That there was not to be a second University established in London had of course been made manifest two years previously by the instructions and provisions set forth in the Act by which the Commissioners were appointed. The schemes for the foundation of an entirely new teaching University, with the title of "Albert" or later of "Gresham," had failed to attract sympathetic attention in high quarters, and had perished almost still-born; the advocates of a third, by which the existing institution, with its territorially extensive area of influence, should be retained under the title "University of England," while a new federal body controlling higher education within the metropolis should take over the old designation "University of London," had underestimated the fervent pride with which the existing graduates treasured their vested interest in titles which had for over sixty years testified to a high academic standard, attained in many cases under serious disadvantages. A sound instinct and a not ignoble sentiment had together won the day. Apprehension, therefore, of the obvious confusions and overlappings and irritations that would have arisen from the co-existence in London of two degree-giving institutions both enjoying the title of "University" was no longer present. But until the full text of the new Statutes and Regulations had been definitely published it was not possible to forecast the future with any certainty.

At last, however, the long contest was over. The proposals and counter-proposals, the concessions and compromises, the revisions and re-revisions, the cross-currents and oblique currents of heterogeneous oppositions, which marked the long agitation for reform,[1] were consigned to countless waste-paper baskets, and the path of future development was in its main outlines plain for all to see. In what follows I have thought it most profitable, not to summarise the formal language of the Statutes section by section, but to indicate their practical bearing upon the situation at the moment of their promulgation. Similarly, it will be more immediately intelligible if I refer to various bodies by the names commonly used in the University, in preference to the more cumbrous official titles by which they are designated by the Commissioners.

Three Main Departments.

The University as reconstituted was to be neither unitary nor federal nor professorial in the normal sense of those terms, nor of any other single type—indeed, it was to be exceptional in structure in correspondence with the exceptional character of the conditions that had necessitated its reform. It was to be organised, so to speak, vertically in three main Departments—the Internal, the External, and the Extension—each under the immediate supervision of a Standing Committee of the Senate. For convenience' sake, let us take the External first. The Committee in this case, consisting mainly of the representatives of the graduates and known as the External Council, had for its function to advise the Senate upon the various matters that had constituted the province of the old University, the work of which may thus be regarded as having been taken over intact as a going concern. These matters were the superintendence, regulation, and conduct of the several examinations of students—metropolitan, provincial, and colonial, in whatever locality and by whatever methods prepared for their successive tests[2]—the appointment of their Examiners, the recommendation of their courses of study, and their status and interests generally; these were henceforth to be designated "External Students." Similarly, the main business of the Extension Board would be to advise the Senate upon the maintenance within the London area of "University Extension" courses of lectures under the system at that period administered (roughly speaking) by Cambridge in the north and east of England, by Oxford in the south and west, by Manchester in Lancashire, and in London and its suburbs, where there was then no corresponding authoritative body in the possession of machinery for comprehensive higher education of this character, by an independent Society, established for this purpose alone and conducting its own procedure and finance, but advised in the appointment of Lecturers and Examiners by a Joint Board constituted in equal proportions by the Universities of Oxford, Cambridge, and London. To the Extension Board was further to be entrusted the duty of advising the Senate upon the inspection and examination of secondary schools.

Of the three vertically parallel Departments, therefore, the second and third (according to the order in which they were named in the Statutes) were charged with definite and clearly ascertainable functions already for many years in full and experienced operation, though up to that time they had been exercised by different bodies. But it was upon the Department first named in the Statutes that the Commissioners had bestowed the greatest proportion of their labours; and this was the feature of their work that attracted the chief interest of those engaged, corporately and individually, in the higher education of the metropolis. A fresh creation was required to solve the intricate problem and to put an end, definitely and with precision, to the prolonged controversies. There was to be a new body, a Standing Committee entitled the Academic Council, consisting almost entirely of representatives, appointed on a Faculty basis, of the teaching staffs of institutions that were henceforth to be component parts of the reformed University; and the duty of this body would be to advise the Senate upon all matters concerned with the status and interests of "Internal Students"—that is, of matriculated students who were pursuing approved courses of study in "Schools" of the University or in other institutions under its own Teachers.

The Twenty-four Schools.

It is necessary here to explain the signification and content[3] of various terms used in a technical sense in the Statutes as framed by the Commissioners. The "Schools" were to be public educational institutions

* Part II. will appear in the next issue of THE LANCET.

[1] Some account of these, "swift shafts that speak to the initiate," but a bewilderment and almost a stupefaction even to the intelligent reader of to-day who had not followed the controversies at the time, appeared in THE LANCET of September 3rd, 1898 (pp. 591–593).

[2] This phrase is, of course, not applicable to medical degrees, for which evidence of attendance and clinical practice at some recognised Medical School had always been required; but from 1858 onwards all other degrees had been awarded solely by examination.

[3] In giving these explanations I have not used the phraseology of the Commissioners, but have as far as possible set out their meaning in ordinary language.

(that is, institutions not carried on for profit by the proprietors) in London,[4] of established position, with staffs and equipments adequate for the standard required by the University; and the Commissioners themselves designated twenty-four institutions as qualified to be the first enrolled in this category. These were University College in the Faculties of Arts, Laws, Medicine, Science, Engineering, and Economics; King's College in the same six and Theology; Hackney College, New College, Regent's Park College, Cheshunt College, Wesleyan College (Richmond), and St. John's Hall (Highbury) in the Faculty of Theology; the Royal Holloway College and Bedford College in the Faculties of Arts and Science; the Royal College of Science in the Faculty of Science, with the Wye Agricultural College in the branch of Agriculture only; the Medical Schools of St. Bartholomew's, London, Guy's, St. Thomas's, St. George's, Middlesex, St. Mary's, Charing Cross, and Westminster Hospitals and the London School of Medicine for Women in the Faculty of Medicine; the Central Technical College of the City and Guilds of London Institute in the Faculty of Engineering; and the London School of Economics in the Faculty of Economics and Political Science. At each of these "Schools" the Commissioners specified by name and subject such members of the staff as they considered suitable to constitute the first company of "Recognised Teachers"—to the total number (including "recognitions" of the same person at more than one "School") of 440.

In addition to these specially privileged foundations there were a number of others, less elaborately or comprehensively organised, and in most cases concerned only with one or more branches of the purview of the Faculty concerned, which for these or other reasons the Commissioners did not consider worthy of the rank of "School," but which conducted specialised work of the requisite high standard; at these institutions selected Teachers were individually recognised as members of the University staff.[5] To take the illustration which is of special interest to readers of THE LANCET, the Institutions of this kind whose activities fell within the scope of the Faculty of Medicine were the London School of Tropical Medicine, the London School of Dental Surgery, the College of the National Dental Hospital, the Institute of Dental Technology and School of Mechanical Dentistry, the School of Pharmacy of the Pharmaceutical Society, and the Medical Schools of (or Classes at) the Royal London Ophthalmic Hospital, the National Hospital for the Paralysed and Epileptic, the Brompton Hospital for Consumption, and the Hospital for Sick Children. It should be added, to make clear the governing policy of the Commissioners in this matter, that "provisional recognition" was also accorded to fifty members of the staffs of the twelve above-mentioned Schools in the Faculty of Medicine who were engaged in teaching Preliminary and Intermediate subjects, such provisional recognition to be effective until the Senate might be able to provide or secure common courses of instruction for Internal Medical Students in those subjects at some one or more centres under their immediate control. This project, thus tentatively though hopefully put forward by the Commissioners, failed of realisation, as will be recorded later.

But these "Recognised Teachers" were not to constitute by themselves the teaching staff of the re-organised University. It was from the nature of the case manifest that on first getting to work the Internal Department would have no University staff at its disposal, but would on the other hand be concerned with the staffs of two dozen Colleges and other institutions of established position, many of which had been with notable success carrying on work of University rank for half a century or longer. Hence the care with which the Commissioners drew out their scheme for the recognition by the University of individual Professors, Lecturers, and other teachers at these existing foundations, and provided the new Senate with the select nucleus indicated above. It was also manifest that for the fulfilment of its highest purposes the University must in due course have a staff of its own—that is, appointed by itself under its own conditions and working under its own direction. For the creation, however, of such a body—Professors, Readers, and Lecturers, for whom generically the distinctive title of "Appointed Teachers" was prescribed in advance—with Demonstrators and other assistants, considerable time would be required; and in the meanwhile it would be the business of the Senate to encourage a new corporate spirit among the existing staffs (several of which could boast men and women of the highest distinction), and to expedite the work of reconstruction by setting in motion the machinery of correlation and co-ordination further provided by the Statutes. For plainly, if the Internal side of the University was to develope an organic unity and character of its own, there must be established as speedily as possible opportunities for regular and continuous deliberation among those who in their respective departments of study had up to that time been working, if not in isolation, at any rate independently, under their several governing bodies.

Boards of Studies.

This brings us to the consideration of the Boards of Studies, which, with reference to the suggested description of the Internal and External Departments as working in vertically parallel planes, may be regarded as forces operating upon them horizontally. On these bodies the Statutes conferred very extensive powers, for the full appreciation of which it is necessary to understand exactly the position of the higher authorities designed for the University. It will have been observed that, in summarising the functions of the three Statutory Standing Committees, I used in each case the phrase "to advise the Senate upon. . . ." This was not accidental—it indicates a fundamental principle of the new constitution. These bodies were to be purely advisory, not only the supreme government of the University but the entire management of all its affairs, concerns, and property being vested in the Senate alone. This ultimate authority, however, was forbidden by the Statutes to come to any determination upon any matter relating to the Internal or to the External department of its work until it had invited and received a report thereon from the Academic or from the External Council respectively. In order that there might be no question as to the extent of this limitation of the powers of the Senate, the Statutes specified at considerable length the matters to which it applied—with such particularity, indeed, that the concluding clause in each case ("generally upon any matter relating to the Internal [*or* External] Students") appears almost redundant. On the same principle, the two Councils were themselves instructed to invite and receive reports from the relevant Board or Boards of Studies before tendering to the Senate advice upon "any matter relating to courses of study, provision for teaching or research, examinations and the appointment of Examiners, or the granting of degrees or certificates of proficiency." This precise and rigid restriction of the powers, first of the Senate and secondly of the two Councils, in all matters that concerned the education and examination of Internal Students and the examination of External Students, was of the essence of the reconstruction of the University. For this reason, and as indicative of the scope of its operations as conceived in the mind

[4] "Within the administrative County of London including the County of the City of London" is the official normal limitation for Schools; from this the Royal Holloway College and the Wye Agricultural College were by Act of Parliament specifically exempted. For virtually every other purpose the area within which the University was to work was that of a circle with a radius of thirty miles from its Central Office.

[5] In the complicated nomenclature of the University's reorganisation it was at an early stage found convenient to speak of these institutions at which, not being "Schools," there were, either by this nomination of the Commissioners or later by the action of the Senate, "Recognised Teachers," as "Institutions" *par excellence*, in contrast with "institutions." The expression "Schools and Institutions of the University" thus obtained a quasi-statutory significance.

of the Commissioners, and further in view of the lines upon which the work of the Senate will later be shown to have developed during the past twenty-seven years, it appears desirable to set out in this place the titles of the original Boards of Studies. The list drawn up by the Commissioners and by them recommended for immediate appointment consisted of thirty-two :—Theology ; the Greek and the Latin Languages and Literatures ; Oriental Languages and Literatures ; Mediaeval and Modern Languages and Literatures ; History ; Archaeology and Palaeography ; Philosophical Studies ; Pedagogy ; Fine Art (for all the Fine Arts, exclusive of Music but inclusive of Architecture) ; Laws ; Economics and Political Science (including Commerce and Industry) ; Music ; Preliminary Medical Studies ; Intermediate Medical Studies ; Advanced Medical Studies ; Dentistry ; Pharmacy ; Hygiene and Public Health ; Mathematics (including Astronomy and Navigation) ; Physics ; Chemistry and Chemical Industries ; Geology ; Botany ; Zoology and Comparative Anatomy ; Physiology and Experimental Psychology ; Ethnology ; Geography (Physical, Political, and Commercial) ; Civil and Mechanical Engineering ; Electrical Engineering ; Marine Engineering and Naval Architecture ; Mining and Metallurgy ; Agriculture.

By its breadth of range this scheme secured to those concerned with every subject of University study ample and definite opportunity of making their views—the views not only of skilled specialists but also of practical instructors—known to the Senate through the two correlating Councils. Each Board was to consist in the first place of the leading Teachers of that particular subject of study in the several constituent Schools, and to these the Senate were empowered at their discretion to add external experts—that is, persons not directly associated with the teaching work of the University—to the number of not more than a quarter of the total membership of the Board. It was further specifically provided, for the protection of the interests of the smaller Institutions, that Teachers not attached to any School should be adequately represented on each Board ; and, in addition, as a matter of practical convenience, that any two or more Boards might, and when requested by the Senate should, meet and act in concurrence and render a joint report. Nor was the function of the Boards limited to consideration of and report upon matters specifically referred to them from above ; any Board might itself originate proposals. In so far, therefore, as the actual details of curricula and schemes of examination were concerned, the Boards of Studies were definitely invested with prerogative and far-reaching powers ; and upon them in the first instance—upon each in its own province—would lie the peculiarly delicate and responsible task of suggesting by what means the degrees conferred upon Internal and upon External Students, whatever variations in detail this distinction might entail, should represent as far as possible the same standard of knowledge and attainments—an essential feature of the new constitution upon which the Statutes laid special stress.

The Eight Faculties.

Running roughly parallel with the Boards of Studies, above them in the hierarchy, but not so powerful in that there was no obligation imposed upon the two Councils and the Senate to consult them, were to be the eight Faculties—Theology, Arts, Laws, Music, Medicine, Science, Engineering, and Economics. In this connection, as generally (though not invariably) throughout the Statutes, the term "Faculty" is used to designate, not (as commonly elsewhere) an administrative department of the University, nor even the whole body of persons engaged in teaching a particular subject or group of cognate subjects, but a judiciously select number of such persons, membership of the relevant Faculty (in certain cases more than one) being conferred either by original nomination by the Commissioners, or by subsequent "appointment" (as contrasted with "recognition") to a Teachership, or, in the case of other Teachers, by individual admission by the Senate. Of these three categories of membership the first and second were definite ; the conditions of admission under the third were deliberately left to the discretion of the Senate, the only condition imposed by the Statutes being that "as far as possible all sections of Teachers" should be represented. By one of their Regulations the Commissioners nominated 8 persons to be the first members of the Faculty of Theology, 31 of that of Arts, 10 of that of Music, 162 of that of Medicine, 50 of that of Science, 13 of that of Engineering, and 10 of that of Economics. For the constitution of these original nuclei the Commissioners appear to have confined their selections to the heads of departments and important sub-departments at the Schools and Institutions severally concerned, leaving it to the Senate, who would be able to act upon more immediate knowledge, to strengthen and maintain them in accordance with the successive conditions and circumstances of each case and the general development of the University at large. What might appear to be the disproportionate size of the Faculty of Medicine was of course due to the coincident facts that it was concerned with no less than twelve original Schools and that there are a considerable number of separate subjects in the complete medical curriculum. The Faculty next largest in number of Schools was that of Theology, with seven ; but these were in nearly every case small in respect of both staff and studentry, and the curriculum for degrees is less extensive. In Arts (with four original Schools) and Science (with five) the number of subjects is much larger ; smaller, but still considerable, in Engineering (with three Schools) and in Economics (mainly but not exclusively centred at one) ; while Music, as a single subject complete in itself, formed no part of the scope of any of the Schools but was taught at three Institutions. It will be observed that the Faculty of Laws, specified in the Statutes as one of the original eight, was not at that time brought into actual existence. As they pointed out in a Report accompanying their Statutes, the Commissioners had hoped, in view of the fact that within the British Empire almost every civilised system of law was to be found in active operation, and of the consequent special value to numerous British public officials of a philosophical study of Jurisprudence, to complete their general scheme by establishing such a Faculty together with, and on principles similar to those applied to, the other seven. But the four Inns of Court declined either to become Schools or to recommend persons for recognition as original Teachers ; and "to their great regret" the Commissioners declared that they had not been able "at present" to constitute any "effective Faculty of Laws." This failure of their efforts was, they added, the more lamentable because the University of London was "honourably distinguished by being the first University in this country which conferred degrees in Laws after and as the result of adequate examinations," and at the date of their Report had on its Register about 500 Bachelors of Laws and 70 Doctors of Laws. But in face of the refusal of all co-operation by the four Inns of Court they felt that they must leave this deplorable gap in the fabric of the reformed University, and could do no more than recognise a few individual teachers of various branches of the subject at University College.

By this elaborate machinery of Boards of Studies, Faculties, Recognised and Appointed Teachers, Schools and Institutions, and Academic Council—each body furnished with its definite place and powers in the general scheme—the Commissioners produced what was confidently expected to be an effective solution of the problem that had for many years engaged the anxious attention of those responsible for the conduct of higher education in London. For no feature of the manifold agitation for reform had been more urgently accentuated than the discontent

of the teaching bodies at the complete detachment of the examining authority from themselves, who had thereby in many cases had imposed upon them uncongenial lines of study and limitations of their range of instruction. This interference with the freedom essential to advanced teachers had become intolerable, and it had been generally recognised that there could be no permanent satisfaction until the whole of the academic resources of the metropolis had been harmoniously organised into one authoritative body. A definite and coherent—though necessarily complicated—scheme had at last been brought to the birth; and, as I have said, the prevailing sentiment on the promulgation of the Statutes and Regulations was one of relief. This was, however, in certain cases shadowed by apprehension—of two kinds. On the one hand, some of those who up to that date had won or who hoped in the future to win their degrees by private study or from provincial or colonial Colleges feared that their status might suffer from the establishment of a teaching University in the metropolis. On the other, there were among the governing bodies and staffs of the Colleges and Institutions which were henceforth to form integrally component parts of the re-organised University some who were doubtful how the new apparatus would actually work when set in motion. It would be no small element in the gravity of the task entrusted to the new Senate to remove this apprehension and distrust, so that the new machine might be worked to the utmost of the powers and goodwill of all concerned for the furtherance of the purposes which they were appointed to execute.

The New Senate.

The body upon whom in the last resort this prodigious burden was laid, inheriting from its predecessor the title of Senate, was to consist of 56 persons:—the Chancellor and the Chairman of Convocation, both elected by Convocation; four persons appointed by the Crown; 16 by Convocation[6]; two by the Royal College of Physicians; two by the Royal College of Surgeons; two by University College; two by King's College; one by each of the four Inns of Court; two by the Law Society; one by the Corporation of the City; two by the County Council; one by the City and Guilds of London Institute; and 16 by the Faculties.[7] It will be observed that this constitution, which in its main features was settled in advance by the Act by which the Commissioners were appointed, was designed to secure, as far as was practicable within the limit of number prescribed, equitable representation for all classes and categories concerned—for corporations and professions, for graduates and teachers, for every main branch of University study, for Internal and External interests.

Such was the composition of the "supreme Governing and Executive Body" of the reconstructed University, which, while inheriting the high and honourable traditions of its earlier history, was in future to occupy a larger sphere and to exercise more extensive functions. It was no longer to be content with examining and setting its hall-mark upon men and women who had been prepared for its tests by other agencies, independent alike of itself and of one-another. To this was henceforth to be added the promotion of research and the advancement of science and learning in the several departments of activity that fell within its purview, and the organisation, improvement, extension, and control of higher education throughout the area specially committed to its charge.

(To be concluded.)

[6] Six of these were to be chosen by the graduates in Arts one to be transferred to the graduates in Divinity as soon as these should number 30), one by those in Laws, one by those in Music, two by those in Medicine and Surgery, and six by those in Science.

[7] Four each by those of Arts and Science, three by that of Medicine, and one each by those of Theology, Laws (when instituted, and meanwhile by the Crown), Music, Engineering, and Economics.

MENTAL DISORDER AND DEFICIENCY.

WORK OF THE BOARD OF CONTROL IN 1926.

THE most important event for the Board of Control in Lunacy and Mental Deficiency last year was its appearance before the Royal Commission, the main provisions of which were summarised in THE LANCET, 1926, ii., 239. The Report[1] for 1926 contains an account of the evidence which was given by the Board and of the extent to which the Commission subsequently gave effect to their recommendations. The Board, for example, recommended in dealing with the "non-volitional" case that the patient should be received without certification, on the recommendation of two medical practitioners, into any approved institution or single care. The conditions proposed were that the Board should be notified and given power of inspection, and that the patient should be allowed to leave on 72 hours' notice if he recovered volition. After six months the treatment could be continued for another six months on the recommendation of two independent physicians. This procedure closely follows that at present in vogue in Scotland. The Commission were unable to recommend the elimination of a judicial authority, although they strongly sympathised with the views of the Board.

Mental Disorder.

The number of notified insane persons under care in England and Wales on Jan. 1st, 1927, was 136,626, an increase of 2743 on the preceding year's total. This increase is greater by 161 than the average increase for the last five years, and shows that the yearly toll of insanity is on an ascending curve. There is, in the Board's opinion, no evidence that the incidence of mental disorder is increasing; but the normal growth of the population is making the problem of accommodation an acute one, about which the Commissioners are justly anxious. Apart from ordinary ward space, most mental institutions need admission hospitals, sick wards, wards for excited patients, and laboratories. A slight relief is being afforded by the reopening of the L.C.C.'s Colony at Epsom for 429 patients, by the provision of a 269-bed annexe for females at Springfield Hospital, Malden, and by the opening of the new home and training-school for nurses at Barming Heath, whereby 160 beds will be released. This expansion does not, however, cover the growth in the number of patients, and, in the words of the Board, "the County and Borough Mental Hospitals must be regarded as full." If serious overcrowding is to be avoided, they say, energetic measures are necessary. It appears from the Report that Poor-law accommodation for harmless patients is not being used nearly as fully as it might be, but that even if it were the special types of accommodation mentioned above would still be necessary.

The recovery-rate for County Hospitals was 30·3 per cent. and for Borough Hospitals 38·5. The combined death-rate was 7·3 per cent.; the fall has been continuous since 1922. The post-mortem rate was 68·1 per cent., varying from 100 per cent. at Cumberland to 7 per cent. at Middlesbrough and 9 per cent. at Croydon. Enteric fever occurred in 33 hospitals as against 35 in 1925, showing the usual predilection for females. The Board recommend prophylactic inoculation in hospitals where the disease occurs every year, as an adjuvant always to hygienic measures and laboratory facilities. 515 cases of dysentery—more than double the 1925 total—were notified, with, however, only 98 deaths against 79. The rise is partly, but not entirely, due to greater accuracy in diagnosis. Dysentery attacks the staffs much less than typhoid. The incidence-rate of tuberculosis fell from 11·8 per cent. to 9·7 per cent. during last year, and the death-

[1] H. M. Stationery Office. Part I., 2*s.*; Part II., 9*s.*

rate from 8·6 per 1000 to 8·0. The death-rate from pulmonary tuberculosis was 6·6 per cent., the lowest yet recorded. The number of patients who committed suicide was 55, but only 27 of these were in residence. This is a decrease of one in the residents and an increase of three only in those on leave or trial—a noteworthy result considering the large numbers now allowed these privileges. Two occurred at branch houses, a circumstance on which the Board comment unfavourably. Voluntary boarders have increased by about 8 per cent. throughout the country. The Board report very favourably on the standard maintained by the licensed houses.

Mental Deficiency.

The shortage of accommodation for mental defectives, upon which the Board reported so gravely last year, has been still further accentuated. No new institutions have been provided, and the total increase is 226 beds only. The total number of beds available is 5301, against the estimated defective population of 40,000 to 45,000. The Board are still urgently inviting schemes for providing extra room. The reluctance of local authorities to meet the necessities of the situation is, in the Board's view, not due so much to ignorance or to unwillingness to perform their duty, as to the heaviness of the rates already levied. It is not sufficiently recognised that the community has to pay for the support of its feeble-minded whether they are housed in special institutions or allowed to remain at large. The necessity for immediate action was equally well recognised by the Departmental Committee on the Treatment of Young Offenders, which sat early this year and whose report the Board quote. Five of the seven local authorities who were reported last year to have acquired estates have now submitted schemes, and five more bought estates last year, including Newcastle-on-Tyne, whose purchase included a large and easily adaptable building which will, it is hoped, soon be available for some 300 patients. The Board recommend all local authorities whose population is not large enough to need a full-sized colony to combine with their neighbours without delay. If all the existing schemes mature in two or three years the situation will be substantially better, but they are only local measures, and many authorities will still be without accommodation even for the most urgent cases. The Board repeat their advocacy of the colony system, describing the organisation at Monyhull, Birmingham.

Marriage and Sterilisation of Defectives.

The Board are naturally uncompromising in their condemnation of marriage among mentally deficient persons, and advise the publication by local authorities of the facts concerning this abuse, so as to prepare the way for legislation. That public opinion is still ignorant of the necessity for preventing defectives from marrying is shown by the many reports from local authorities of the refusal by justices of petitions for detention in order to allow pregnant or even non-pregnant defective girls to marry. The Report emphasises the need for selecting more carefully the persons to whom marriageable defectives are licensed, and points out the danger of placing defectives under the guardianship of their parents, who too often either deny the defect or deliberately encourage marriage or conceal intimacy. The Board have not altered their views on sterilisation, and reiterate their opinion, published last year, that this measure would not diminish the need for colonies. The idea that many patients are only segregated to prevent them from propagating is considered highly erroneous, and the Report quotes a minute from Dr. Douglas Turner, of the Royal Eastern Counties Institution, who supports by convincing arguments the view that the proportion of defectives whom sterilisation would release from supervision is about 3 per cent. The Report does not touch on the important question of venereal disease, which would be propagated quite as freely, if not more so, by sterilised than by unsterilised defectives.

Statistics.

Improved ascertainment is responsible for much of the increase in the known defective population, both because diagnostic methods have become more accurate and because authorities have become more alive to the importance of the work. The number on record at the end of 1926 was 60,234, a proportion of 1·59 per 1000; this is an increase of 4754 during the year. Of these only 22,739 are under care. Reporting authorities fall into two distinct groups: those who report 2 per 1000 or over, and those who report less than 1 per 1000. The number of the latter group has decreased from 56 in 1925 to 30 in 1926, and only 11 bodies report under 0·45 per 1000. These results point, as the Board maintain, to the advisability of renewed endeavour on the part of some local authorities, and particularly to the realisation by certain local education authorities that their own failure to notify makes a fatal gap in the community's scheme for the continuous care of the mentally defective.

Sixteen new occupation and industrial centres were opened during last year, and 109 more patients attended. The Board call for every effort to increase the average attendances, which are only 63·8 per cent. of the registered numbers, and to raise the numbers at the smaller centres. It is doubtful, they say, whether it is worth spending public money on a centre with an average attendance below six. Only seven out of 74 centres are reported as unsatisfactory, and in six of these the supervisors have no special qualifications.

874 patients were under guardianship at the beginning of this year, 273 more than at the beginning of 1926. This increase is probably due to the new powers given by the Amendment Act of 1925, and the Board request local authorities to exercise the greatest care in choosing guardians, a duty not always satisfactorily performed.

The percentage of successful discharges of high-grade defectives was 14, as against 7, 11, and 12 in the three preceding years. The number of idiots and imbeciles in mental hospitals is still 150. Apart from the inconvenience they cause there, they miss the training most of them are capable of receiving.

After an appreciation of the work done by the Central Association for Mental Welfare during the year, the Report gives the number of admissions to county and borough mental hospitals for encephalitis lethargica as 135, and to mental deficiency institutions as 70. The total since 1918 is now 384.

NATIONAL HEALTH INSURANCE MEDICAL BENEFIT.

NEW PROCEDURE AS TO CHANGE OF DOCTOR.

AN alteration of the terms of service of insurance practitioners has been notified by the Ministry of Health to the clerks of Insurance Committees who will advise practitioners in the following form:—

Under the powers conferred on them by Clause 2 of Part I. of the First Schedule to the National Health Insurance Medical Benefit Consolidated Regulations, 1924, the Insurance Committee have decided, with the Minister's approval, and with effect from Oct. 1st next, to alter accordingly the terms of service of practitioners who are under agreement with them, and notice is hereby given to you that on and after this date the provisions of these regulations will form part of the terms and conditions on which insurance practice will be carried on in the Insurance Committee's area, and in so far as they affect the rights and obligations of insurance practitioners shall be deemed to form part of the practitioner's terms of service.

As from Oct. 1st, 1927, an insured person whose name is already included in the list of an insurance practitioner in the district in which he is residing, and who desires to apply for acceptance by another

practitioner, may either transfer with the consent of both practitioners, notified by their signatures on the appropriate space of the medical card, or with the authorisation of the Insurance Committee, which will be given as a matter of right but with effect only after the expiry of 14 days after application. Under the latter alternative the insured person must send to the Insurance Committee his medical card with a letter stating his intention to transfer, and the medical card will be returned to him with a slip attached authorising transfer after the appropriate date. This slip should be completed by the insured person and signed and dated by the practitioner accepting him for treatment. The card with the slip attached should then be forwarded by the practitioner to the Committee. Acceptance cannot be registered until the date named, and in the meantime the insured person should continue to obtain treatment from the former practitioner.

A new form of medical card is being prepared which will contain instructions as to the new procedure, but it is not possible, for reasons of economy, to make a general issue of new cards to all insured persons. Cases will therefore occur in which insured persons in possession of old medical cards will apply as at present for acceptance by a new practitioner. In such cases you are requested to be good enough to inform the insured person that, as he is already on the list of another practitioner in the district, it is necessary that he should obtain either the written consent of the latter to the transfer or the authorisation of the Insurance Committee. The practitioner on whose list the insured person is included can give his consent in cases where old cards are presented, by writing across Part A the words " I consent to transfer " and appending his signature and the date. The insured person and the new practitioner should then complete Part B. The new style of medical card will provide a space Part C to be completed by both practitioners, in cases where transfer is made by consent.

To assist the Committee in bringing the change of procedure to the notice of insured persons, I am to request you to be good enough to exhibit the accompanying poster containing the new instructions in a prominent place in your waiting-room. Further copies of the poster can be obtained on application to the Committee.

I am to add that the new regulations do not in any way affect the existing procedure regarding the acceptance of persons not already on the list of another practitioner practising in your district, of temporary residents, or of persons on the lists of approved institutions.

Text of the New Regulations.

16.—(1) An insured person, other than a member of an institution or a person who is permitted or required to make his own arrangements for obtaining treatment, may at any time make application for acceptance by an insurance practitioner notwithstanding that he is at the date of application included in the list of another practitioner, and if accepted shall forthwith be entitled to obtain treatment from the practitioner to whom application has been made.

Provided that if the insured person is at the date of the application included in the list of another practitioner and has not removed permanently or temporarily outside the district within which the practitioner has undertaken to provide treatment the application of such insured person shall only be accepted if either :—

(*a*) both the practitioner in whose list the insured person is included and the practitioner to whom he applies for acceptance consent to the transfer, and such consent is signified by the practitioners in accordance with the instructions printed on the medical card ; or

(*b*) the insured person has forwarded to the Committee his medical card together with a notice of his desire to transfer and not less than fourteen days after such notice is received by the Committee the insured person and the practitioner to whose list he proposes to transfer have signed a statement in a form approved by the Minister and issued by the Committee indicating the agreement of the insured person and the practitioner that the transfer should be effected, which form shall be attached to the medical card by the Committee.

Poster to Exhibit in Waiting-room.

The poster (referred to above) regarding change of doctor is couched in the following terms :—

After Oct. 1st, 1927, if you wish to change your doctors and if you are still living in the district in which your present doctor practises you should proceed as follows :—

Either (1) You may transfer with the consent of your present doctor and of the new doctor ; in that case you must take your medical card to be signed by both doctors, and leave it with the doctor to whom you wish to transfer.

Or (2) You may send your medical card to the Insurance Committee with a letter stating that you wish to change your doctor. It is not necessary to give the reasons why you wish to change. The card will then be returned to you with instructions as to when and how you may transfer. Until you have complied with the instructions sent to you regarding transfer, you should continue to obtain treatment from your present doctor.

If you have not chosen a doctor, or if you have removed either temporarily or permanently from the district in which your present doctor practises, it is not necessary for you to write to the Committee. All you need do is to take your medical card to any insurance doctor you wish to choose. If you are not in possession of a medical card you should complete a form of application (Form Med. 50) to be obtained at the nearest post office and send it to the Committee.

Postage must be prepaid on all letters to the Insurance Committee.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Progress of Housing.

IN 1928 the question of housing subsidies of every sort falls to be reconsidered, Scotland having obtained an extra year, since, for sufficient reasons, housing progress was not equal to that of England. But at last Scotland seems to have got into her stride, and the large programme projected by the Scottish Housing Commission is in a fair way to be realised. During 1927 the various housing schemes, including those for slum clearance, have begun to bite into the mass of arrears. It is noticeable that in the course of eight years Scotland has largely ceased to be a stone-house country, and has largely become a " brick-and-harl " or cement-block country, although Aberdeen has stuck almost entirely to granite and no Aberdonian would wish it otherwise—at least, in the main areas of the city. But on its fringes and particularly in Deeside, which for seven miles on the north is thickly peopled with villas, " brick-and-harl " or cement-block is making an impression. Elsewhere in Scotland brick and cement can still undersell stone, in spite of the innumerable quarries, and what Carlyle and his mason father would have said of this decline of the mason's craft can be guessed from the Latter-Day Pamphlets. But Carlyle could not have failed to perceive that the country has many thousand more houses than it boasted ten years ago, when the Scottish Housing Commission reported in a document that was not shelved.

The monthly returns for 1927 show that the number of houses finished has not once fallen below 1000 per month, and the average approaches 1550. If this rate is maintained for the next five months, the year will have the handsome record of 18,500 houses, and to these may be added 2500 steel houses erected under the direct control of the Scottish Board of Health. If we total the houses finished, those now building, and those already tendered for (including subsidised " private enterprise " houses), we get a number approaching 115,000 houses, not including the many structures erected without subsidy.

The One-room House.

The lessons of Dr. J. Burn Russell's famous lecture or sermon on " Life in One Room," which prompted a cardinal chapter in the Report of the Housing Commission, is brought to memory by Dr. A. S. M. Macgregor, the present medical officer of health for Glasgow, in his annual report. For this includes a special inquiry by Dr. J. A. Wilson on the age-factor and housing-factor in the incidence of pulmonary

tuberculosis in the east end of Glasgow. Dr. Wilson finds that a marked and rapid fall has taken place in the extent to which adults over 25 years of age are affected. He notes that in the case of males an increase in the size of house is associated with a diminished incidence of the disease, most marked in the young adult and at ages from 46–65 years. As between the one-room and the two-apartment house, the two-apartment house shows a greater incidence at ages 11–15 and 21–25. At all other ages, the one-room house has the greater incidence. In the case of females, at all ages, except 6–10 years and over 66 years, the improvement in the housing status is represented by a marked decline in incidence. If we take the one- and two-apartment houses as against the three-apartment, the decline in incidence is very strikingly shown in the three-apartment house. To those familiar with the area investigated, the "functional" difference between the one-apartment and two-apartment house is largely nominal; but, even so, the two-apartment house scores. This investigation emphatically confirms the Royal Commission's chapter, in which the many Glasgow investigations were fully recognised. The disconcerting fact remains that in this area the one-apartment houses rise to 26 per cent. of the whole, the two-apartment houses 53 per cent., the three-apartment 16 per cent., while only 5 per cent. of the houses are of four or more rooms. Thus 79 per cent. of the houses are of one or two apartments. Dr. Wilson comments: "These graphs, it is suggested, demonstrate in a forceful way the important bearing of housing on the incidence of this disease, the larger houses being associated with a diminished incidence in most age-groups. Much has been written in condemnation of the one-apartment house, and if further condemnation were needed the material is to be found in these results. But it has to be remembered that the house, in an industrial area, is only a reflex of the economic condition of the inhabitants, so that any scheme of prevention must deal with the problem from both angles." This fresh investigation deserves minute study.

The McKelvie Isolation Hospital, Oban.

On the occasion of the opening on Sept. 8th of the new pavilion attached to this hospital, Sir Leslie Mackenzie, as a member of the Scottish Board of Health, delivered an address in which he testified to the great generosity of the original founder, the late Dr. R. B. McKelvie, and the maintenance of civic spirit shown by Mr. Macpherson and his sister in providing funds for the extension and equipment of the institution. He reminded his audience that Dr. McKelvie's first gift of £1000 was later increased to £1500 when the estimate of the cost of erecting the fever block had to be revised. During the lapse of 30 years new needs have been revealed, and these are being met by the recent extension, so that Sir Leslie Mackenzie was able to congratulate the corporation of Oban on now possessing, with its recent addition, an effective modern institution of 42 beds. Sir Leslie Mackenzie closed his address by reviewing the situation brought about, especially in urban communities, by the compulsory notification of infectious disease, made compulsory in Scotland just after the foundation of the McKelvie Isolation Hospital. He said:—

"It is 30 years since compulsory notification was made universal in Scotland. This was done through the Public Health Act of 1897. The ordinary and well-known infections like typhoid fever, typhus, small-pox, scarlet, diphtheria, erysipelas, puerperal fever, and some others were subjected to compulsory notification. Since that time many other diseases have been added, and the list of notifiables now approaches 30. Some have come into the list at one date and some at another. Notification applies perfectly to some and imperfectly to others. But look at the broad fact. In the 30 years since 1897, the medical men have notified 1,450,818. Of these, 770,000 have been removed to hospitals under the management or control of the local authorities for public health. These vast numbers will give some idea of the problem that constantly faces the Public Health Local Authorities of Scotland, which at present number over 300. Take one or two special diseases. In these 30 years, there were notified 137,705 cases of pulmonary tuberculosis. Of these, 66,122 were removed to hospitals or sanatoria. But notification has applied to tuberculosis only since the year 1906, when notification was voluntary, and compulsory since about the year 1910. The numbers notified rise as high as 9000 a year, though recently there has been a falling off until in 1926 the number notified was 6669. Non-pulmonary tuberculosis has been notifiable since 1914. The total notified in those 13 years has been 60,454. Of these 17,232 were removed to hospital. The totals for pulmonary and non-pulmonary tuberculosis were: 198,159 cases notified, 83,354 cases removed. The disease is going down, but with those massed figures before us we can realise how much there is still to do. Take, now, typhoid fever. In the 30 years there were notified nearly 63,000 cases. But whereas in the early years the notifications ran up as high as 5600, the notifications in the last ten years have never, in a single year, exceeded 800, and in some years the notifications have fallen below 400. Obviously, typhoid fever is now under effective control. As to typhus fever, even in 1892 it was comparatively rare. Now we have had at least one year in the 30 without a single case, and one year the notifications were as low as two, although the disease crops up in little outbreaks unexpectedly still. As to small-pox, it is enough to say that in 1926 only one case of small-pox was notified. This year the record will not be so good, but small-pox is also under effective control. Of scarlet fever, the numbers notified in the 30 years approached 530,000. The disease is still very widely prevalent, but, thanks to improved hospital accommodation and improved nursing, the death-rate has remained low. Of diphtheria, the total numbers in 30 years were about 207,000. It is still too prevalent, but the new methods of dealing with scarlet fever and diphtheria are already beginning to have an effect, and as the generation goes on the effects will be still more manifest. . . . In the year 1919 acute primary pneumonia and acute influenzal pneumonia were subjected to compulsory notification. In the eight years since then there have been notified nearly 84,000 cases. Pneumonia, as has been shown in detail in the report of the Scottish Board of Health for 1925 and again in 1926, is one of the most dangerous and fatal and prevalent of all the diseases in Scotland. The large local authorities have treated many thousands of cases, and although it is yet too soon to draw conclusions, there is little doubt that the terrible death-rate from these forms of lung disease will gradually yield to the better management and nursing possible in well-equipped hospitals."

The new extension has been made especially to meet the problems presented under Maternity Service and Child Welfare schemes.

UNITED STATES OF AMERICA.

(BY AN OCCASIONAL CORRESPONDENT.)

The Negro Population.

Dr. Louis L. Dublin, of the New York Metropolitan Life Insurance Company, has recently compiled some statistics about the negro in the United States, and publishes them, together with his conclusions, in the *American Mercury* for September. The first figures relating to the coloured population were, he says, collected in 1790, when there were 757,208 negroes in the country. In 1920 the number had increased to 10,463,131, but whereas in 1790 the negroes amounted to 19·3 per cent. of the total population, in 1920 they amounted to only 9·9 per cent. The health conditions of the negro in America have improved almost pari passu with those of the white man. Dr. Dublin's figures show that the expectation of negro males at 50 is only a year less than that of white males, and of negro females only a little over two years less. According to the books of the Metropolitan Life Insurance Company, in 16 years the mortality record of the coloured policyholders showed a decline of 16·3 per cent. Marked improvement has been exhibited with regard to deaths from tuberculosis, pneumonia, and communicable diseases, though certain degenerative diseases continue to be very prevalent. In the cities and more especially in the northern cities, to which the negroes have emigrated, there has been generally an increase in the death-rate and a decrease of the birth-rate, and it is only in the rural districts of the south that there is now an appreciable excess of births over deaths. Dr. Dublin estimates that the negro population in A.D. 2000 will be about 14,500,000

but as the total population of the United States at that date should have increased to 185,000,000 or thereabouts the coloured people will constitute a little less than 8 per cent. of the total.

Industrial Accidents.

The American Engineering Council has published a report on its national safety and production survey, stating that industry must free itself from unnecessary waste by using modern safety methods to decrease accidents. The rate of production per man-hour, for the industrial groups studied, was 14·4 per cent. higher in 1925 than in 1922, and the rate of accident frequency per man-hour was 10·4 per cent. lower in 1925 than in 1922. The rate of accident severity per man-hour, however, was 2·5 per cent. higher in 1925 than in 1922. Among other recommendations made, the report suggests that the same managing direction and control be given to decreasing industrial accidents as is given to increasing production, and that the executives of plants which have high accident-frequency and accident-severity rates should initiate, direct, and control ways and means of reducing these rates at least to the level of other plants in their industry.

Increase of Diphtheria in New York.

The Department of Health for New York State has issued a report in which it is stated that diphtheria has increased from 69 to 79 cases per 100,000 inhabitants during the first six months of the year. A similar increase has been noted in New York City.

The late Dr. Lewis.

Dr. H. Edwin Lewis, who died on August 6th, was for almost twenty years managing editor of *American Medicine*. Born at Providence, Rhode Island, in 1875, he graduated from the University of Vermont Medical Department in 1897, and went to McGill University, Montreal, for post-graduate study. After practising for some years in Burlington, specialising in tuberculosis, and serving for several years on the Vermont State Tuberculosis Commission, he came in 1906 to New York City, where he combined medical practice with the editorship of the *International Journal of Surgery*. In 1908 he was made managing editor of *American Medicine*—a journal founded and edited by the late Dr. George M. Gould. A talented writer, Dr. Lewis was also an excellent business man, and he was for a time President of the American Medical Editors' Association. Throughout his life he laboured under the burden of ill-health and physical disabilities, and the fact that he succeeded in spite of this handicap is a proof of courage and perseverance.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 10TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 146 (last week 111); scarlet fever, 1617; diphtheria, 997; enteric fever, 107; pneumonia, 478; puerperal fever, 32; puerperal pyrexia, 99; cerebro-spinal fever, 10; acute poliomyelitis, 38; acute polio-encephalitis, 3; encephalitis lethargica, 30; continued fever, 1; dysentery, 8; and ophthalmia neonatorum, 102. No case of cholera, plague, or typhus fever was notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 4 (1) from enteric fever, 16 (2) from measles, 6 (0) from scarlet fever, 14 (4) from whooping-cough, 24 (5) from diphtheria, 78 (10) from diarrhœa and enteritis under two years, and 21 (5) from influenza. The figures in parentheses are those for London itself.

With regard to the death from small-pox reported in the Registrar-General's weekly return last week (No. 35) we understand that the death referred to was that of a man aged 77, who was admitted to the Doncaster Small-pox Hospital on July 12th and discharged cured on August 20th. Death took place on August 28th, the cause of death being stated thus on the certificate: I. (*a*) toxæmia; (*b*) gangrene of right foot; (*c*) small-pox.

Obituary.

SIDNEY RAWSON WILSON, M.B., B.S. LOND., M.SC. MANCH., F.R.C.S. EDIN.

WE have already announced the death of Dr. S. R. Wilson, senior anæsthetist to the Royal Infirmary, which occurred at his home in Manchester on Sept. 12th. Dr. Wilson had long been investigating the proportion of gas and oxygen which gives the best results, and the physiological problem whether the anæsthetic properties of gases are due to limitation of oxygen or to a special action on nerve-cells. At the time of his death he was planning a crucial experiment on this point. Though he did research work at the hospital he was also accustomed, in spite of warnings, to make observations on himself, and his death seems to have been due to premature exhaustion of an oxygen cylinder during such an experiment.

"S. R.," as he was familiarly called, came of a family long connected with Manchester. His grandfather, George Wilson, took a leading part in the Free Trade movement of the middle of the nineteenth century, and was a strong supporter of Joseph Jordan, one of the founders of the Manchester Medical School—a fact of which the younger Wilson was very proud. His father is Dr. A. C. J. Wilson, of Penistone, and S. R. Wilson was born in that town 45 years ago. On going to Manchester University in 1900 he soon showed his qualities, and carried off most of the prizes of his time. Even as a student he had an extensive practice in coaching, taking in hand fellow students in subjects he had himself just passed or in the very subjects he was studying. He even coached in subjects which were not directly in his own line, learning up the work shortly before he taught it. By his clearness of comprehension and his simple way of putting things he made medicine more easy for his fellow students than could the acknowledged teachers. Careless in his dress, and outspoken in his criticism, he was somewhat of a free lance in his student days. Soon after qualification, with a long series of academic triumphs to his name, he took up anæsthetics and in his specialty worked up to a leading position in Manchester, becoming senior anæsthetist to the Royal Infirmary. He was especially interested in the use of nitrous oxide, and in recent years in ethylene, but during the last year of his life he spent much time in studying some unexpected deaths following the use, as he claimed, of impure ether.[1] He thought deeply, and his brain was always engaged on the problems which anæsthesia presents. He was also a forceful teacher, and large numbers of his former pupils, in mourning his loss, will remember how much they owe to him. In the University of Manchester he held the post of lecturer in applied physiology, and he was deeply interested in the history of his old medical school and in any problems that affected its welfare. Hypnotism and psychology were favourite studies, and he applied hypnotism for anæsthesia to the small extent that opportunity provided. In 1922, with Mr. A. H. Southam, he published a paper on the cancer of the scrotum which occurs in mule-spinners. This subject he had discussed many years previously with the late Mr. George A. Wright, and had been studying till sufficient material was accumulated.

Personally, he had a sort of rugged charm. Though a fighter and by no means fine spoken, he was always sympathetic and always ready to help. He had a distinct wit, and when in vein he could be intensely amusing. Those who attended his lectures on the history of anæsthetics came away thinking them the most interesting and the most clever they had heard.

Dr. Wilson married the daughter of Mr. John Mitchell, who survives him with a son and a daughter. The funeral took place on Sept. 16th at the Manchester Southern Cemetery, after a largely attended memorial service at St. Chrysostom's, Victoria Park.

[1] THE LANCET, 1927, i., 1117; and ii., 88.

CHARLES EDWARD PAGET, M.R.C.S., D.P.H.

Mr. C. E. Paget, whose death occurred on Sept. 11th, was for 28 years medical officer of health for the County of Northampton, and wrote a number of books on hygiene. Born in 1858, he was the son of Sir George Paget, F.R.S., Regius Professor of Physic in the University of Cambridge, and was educated at Charterhouse and St. Bartholomew's Hospital. At one time he acted as secretary to his uncle, Sir James Paget, F.R.S., but soon after qualifying in 1882 he decided to devote himself to public health work and was appointed medical officer of the Westmorland combined sanitary districts. The duties of this office he combined with hon. secretaryship of the Epidemiological Society for seven years, but after succeeding Sir John (then Dr.) Tatham as medical officer of health for Salford in 1889, he was obliged to resign this extra work, though he later became a member of the Society's Council. While at Salford Mr. Paget —as he preferred to be called—was elected president of the North-Western branch of the Society of Medical Officers of Health, and was lecturer in public health at Owens College and examiner in the Victoria University of Manchester. Already he had published two handbooks on the subject, "Healthy Schools" (1884) and "The Construction of School Sanatoria" (1887), and had become widely known as a capable and thoughtful worker when in 1897 he was appointed the first medical officer of health and school medical officer for Northamptonshire. Here there was a clear field for his energies, though he had to contend with the opposition of those who regarded a county medical officer as an unnecessary luxury. His manner and methods were well calculated to overcome such obstacles. Modest to a degree, he soon became popular among all classes, whilst his enthusiasm for improvement did not narrow his outlook on the problems to be faced. He was especially interested, perhaps, in the welfare of infants and children, and it is a tribute to his efforts that the infant mortality of the county decreased during his term of office from 159 to 52 per 1000 births. During the same period the general death-rate fell from 15·57 to 11·37. Mr. Paget's annual reports were always lucid, and he wrote a number of useful reports on special subjects, notably fevers, besides editing the lectures of his father, with a memoir. He resigned his appointment last year, and was succeeded by Dr. Meredith Davies. Soon after his retirement he was elected an honorary member of the Association of County Medical Officers of Health, and this recognition of his work, he said at the time, gave him the greatest pleasure of his life.

Mr. Paget married Ethel, daughter of Canon W. H. Brandreth, and she survives him. Their only child, Lieut. G. G. B. Paget, of the Northamptonshire Regiment, was killed in action in 1914.

CHARLES SAMUEL BREWER, O.B.E., L.R.C.P. EDIN.

Dr. C. S. Brewer, who had been in poor health for seven or eight years, died on Sept. 7th at his home in Birkenhead. Most of his life was spent in that neighbourhood, for after studying at the Liverpool School of Medicine he was appointed house surgeon at the Birkenhead Borough Hospital, and soon afterwards took over a practice in the town, where he remained for the rest of his life. His period of active practice was nearly forty years, but was interrupted for a time by the late war, during which Dr. Brewer served as staff-surgeon on H.M.S. *Eaglet*, with the rank of Surgeon Lieut.-Commander, R.N.V.R. He was made an Officer of the Order of the British Empire in recognition of his services. On returning to Birkenhead he resumed the prominent place that he had gained in local affairs, and even after his retirement a few years ago continued to do a great deal to promote infant welfare and other public work. He was a leading Freemason and served for several years on the Birkenhead Town Council. He leaves a widow.

THE LABELLING OF EGGS.

To the Editor of THE LANCET.

SIR,—As a layman who has devoted the major part of his time during the last ten years to the study of eggs, from their dietetic value as a life-giving food, their commercial aspect and their exhibition merits, I should like to endorse and amplify the remarks made by Dr. E. G. Annis in your issue of Sept. 3rd, and previous letters upon this subject.

The intrinsic food value of eggs is not sufficiently known or appreciated by the British public. Until they can obtain new-laid eggs with assurance and confidence that the article purchased is genuinely as represented, so long will the position remain in statu quo—a national scandal. In common justice the consumer has a right to know what he is buying. This obligation has not yet been recognised. The extent to which foreign eggs are being mixed with English is appalling.

Nature ordained that at least one indispensable article of food should be provided for our use safe from the machinations and evil ingenuity of man to adulterate, hence eggs are contained in sealed packets. Yet this very safeguard is utilised as a convenient cloak by the unscrupulous to shelter their deliberate delinquencies. The solution of the problem lies in two directions.

First, legislative assistance is needed—all imported eggs must be marked with their country of origin. It must be enacted that it is illegal to offer for sale bad eggs and stale eggs for new-laid eggs or fresh. Secondly—as producers, men of acumen, acknowledge —there must be a complete reorganisation of marketing and adoption of standard grades. Soiled or dirty eggs must be eliminated. It is easy to see through the objections raised against the marking of imported eggs.

As far as the cost is concerned, the Minister of Agriculture informs us that estimates range from one-seventh of a penny to one penny per dozen; a mere trivial matter in comparison to health, and the cost would fall upon the importer. Poultry keepers do not fear the fair competition of imported eggs, but they do object to the unfair competition produced by mixing and selling these eggs as English new-laid.

I am, Sir, yours, faithfully,

JAMES GATECLIFF.

24, Minnis Bay, Birchington-on-Sea, Sept. 13th, 1927.

MULTIPLE CAVERNOUS ANGIOMATA OF THE SWEAT DUCTS.

To the Editor of THE LANCET.

SIR,—The interesting case recorded by Dr. B. W. Crowhurst Archer in THE LANCET of Sept. 17th (p. 595) recalls numerous descriptions of what may be termed "telangiectasia" of the skin and mucous membranes, whether familial or non-familial, and whether or not accompanied by special tendency to hæmorrhage. I have referred to many such cases in an article entitled Developmental Telangiectatic Hæmorrhage and So-called Telangiectasia.[1] But the case which, in regard to the extensive distribution on the trunk, it seems most to resemble was omitted from my list —namely, the one published under the heading Angiomatosis Miliaris by L. Steiner and H. Voerner.[2] Nevertheless, there are apparently many points of difference between the two cases.

I am, Sir, yours faithfully,

F. PARKES WEBER, M.D.

London, W., Sept. 17th, 1927.

STIMULANTS OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—In your leading article in THE LANCET for Sept. 10th with this heading there appears to be a certain confusion in the mind of the writer as to the identities of the alkaloids of ergot, ergotamine and ergotoxine.

Although it is clear that the experiments made by the authors, whose work is under review, were carried out with ergotamine in the form of ergotamine tartrate, and that their conclusions are based on the results obtained with this salt, your leader writer appears to consider that the pharmacological similarity between the two alkaloids entitles him, by an analogical process of reasoning, to substitute the word "ergotoxine" for "ergotamine" throughout.

We desire to make it clear that there are fundamental differences between ergotamine and ergotoxine. Ergotamine differs from ergotoxine in its chemical composition. Ergotamine is a crystalline substance, whereas ergotoxine has always been described as being amorphous. Ergotamine yields pure crystalline salts suitable for clinical use, and ergotamine tartrate, under the name of Femergin, has been available in unlimited quantities, and extensively used, for a considerable time. The abundant clinical evidence which proves that ergotamine is a powerful and reliable agent appears to be singularly lacking for any other constituent of ergot.—I am, Sir, yours faithfully,

J. FLINT,
Manager, "Sandoz" Scientific and Research Department.

5, Wigmore-street, London, W. 1, Sept. 15th, 1927.

*** Mr. A. Bourne and Dr. J. H. Burn, when discussing the physiologically active substances in ergot, say (*Journal of Obstetrics and Gynæcology of the British Empire*, XXXIV., No. 2, p. 259): "These are (1) the specific alkaloid of ergot, (2) histamine, (3) tyramine. The specific alkaloid of ergot is known as ergotoxin, in which form it was originally isolated by Barger and Carr, and as ergotamine, a pharmacologically identical and crystalline substance isolated by Stoll." In their summary (p. 267) it is stated: "The specific alkaloid of ergot (ergotamine or ergotoxin) exerts a very prolonged action, and appears to be an ideal agent for use after delivery." The leading article to which the above letter refers was designed not to discuss any particular preparation but, in a general way, the specific alkaloid of ergot.—ED. L.

MEDICAL LITERATURE FOR KENYA COLONY.

To the Editor of THE LANCET.

SIR,—With reference to the letter appearing under the above heading in your number of June 4th last (p. 1205), the Branch Council of the Kenya branch of the British Medical Association desires to express strongly its disagreement with the statement made therein, that the medical practitioners of Kenya would gratefully welcome gifts of fairly up-to-date books on medicine and surgery.

The fact is that the medical department of the colony maintains a medical reference library which is accessible to all doctors in the colony. This contains all the best of the most recent medical publications and takes in the majority of the standard medical and scientific journals published to-day. Furthermore, it is probable that the private libraries of medical men in this colony would compare favourably with those of their professional brethren at home.

While grateful for the suggested vicarious generosity of the President of the Victoria League, my Branch Council fears that the statement that medical practitioners in this colony feel a pressing need for text-books of medicine and surgery may be misconstrued into a reflection on their professional efficiency.

I am, Sir, yours faithfully,

J. B. CLARKE,
President, Kenya Branch, British Medical Association.

Nairobi, August 24th, 1927.

CHARLES CREIGHTON.

To the Editor of THE LANCET.

SIR,—May I express my gratitude to Prof. William Bulloch for his remarkable appreciation of a remarkable man contained in THE LANCET of July 30th. No one who has read that scholarly book "The History of Epidemics in Britain" (not *Great* Britain) or who has had occasion to study Creighton's translation of Hirsch's "Handbook of Geographical and Historical Pathology" can fail to have acquired a feeling of respect and admiration for their author—a feeling which the pathetic story of his life, so vividly portrayed by Prof. Bulloch, serves to intensify.

Dr. Charles Creighton was the last of the great miasmatists, and his passing marks the end of an era which, starting some 2000 years ago, gave us Sydenham and a distinguished band of medical philosophers. It is, however, not possible to account for the attitude of detachment adopted by Creighton towards the discoveries of Pasteur and Koch, but, as Prof. Bulloch hints, it may be that modern epidemiologists, as the result of discarding the spirit as well as the letter of his message, have failed to do full justice either to him or to themselves. "We have thrust," wrote Sir Clifford Allbutt, "ancient myth and symbol too much aside as wholly fanciful; we are discovering now that they are apparitions, luminous mists of truth—the edges and bordering lights growing in form from one incarnation to another."

This view, I take it, represents in graceful literary form the standpoint of Creighton, and it may be that the day is not far distant when it will be recognised that the miasmatic concept does, after all, correspond with something in nature. In the meantime it is pleasing to learn that the anxieties of his latter days were relieved by an unsought civil pension—a gift equally honourable to the donor as to the recipient.

I am, Sir, yours faithfully,

C. A. GILL, Lt.-Col., I.M.S.

Simla, India, Sept. 1st, 1927.

DEATH CERTIFICATION.

To the Editor of THE LANCET.

SIR,—It is clear that the majority of us have by this time experience of the new form of death certification; but it is strange to me that it seems so far to have escaped criticism. Apart from the form of certificate and the suggested procedure descriptive of the mode of death, both susceptible of improvement, there is a pitfall for the ingenuous in the mode of certifying. The certificate is to be delivered personally—or it may be posted—by the certifier to the registrar of the subdistrict in which the death occurred. What does this imply? To the ingenuous privacy. He would suppose that having excluded the family circle he should proceed with complete frankness to describe the mode of death along with its every contributory factor. For example:—

(*a*) Hæmatemesis.
(*b*) Cirrhosis of liver.
(*c*) Chronic alcoholism.

With what result? That an outraged relative may confront him the same evening with a copy obtained from the registrar! I make no comment; but I submit that the fact must be recognised.

And then, as to the registrar—his name? address? hours of attendance? These are not necessarily an easy discovery, for they may entail the assistance of postal, or municipal authorities, or of undertakers or any other informed and obliging people. My own practice, for example, happens to lie in not less than six different boroughs; and it is my duty to ascertain when necessary the address of a registrar in, for all I know, any one of a dozen or perhaps a score of subdistricts. What is to be *done* about such things? It may be possible that some of your correspondents can make suggestions; in any case the matter is susceptible of discussion and I should hope of remedy.

I am, Sir, yours faithfully,

PRACTITIONER.

Sept. 12th, 1927.

ESTABLISHMENT OF BREAST-FEEDING IN A BABY SIX WEEKS OLD.

To the Editor of THE LANCET.

SIR,—Since the Chelsea Mothers' Home was opened two years ago some very encouraging results have been obtained, and we have become accustomed to see breast-feeding re-established after a considerable interval. The following recent case was, however, so unusual that it seems worth recording.

Baby D. S. was born on July 16th, 1927; the birth weight was reputed to have been 12 lb. The child was put to the breast in the usual way, but no milk appeared in the mother's breasts by the third day. The midwife then stated that further efforts to suckle the child would be useless; on her advice the child was removed entirely from the breast and artificially fed. Condensed milk, various dried milks, and a proprietary food were tried in turn. Under this régime the child lost weight.

The mother and child were admitted to the Chelsea Mothers' Home on August 25th. Baby D. S., then six weeks old, weighed 10 lb.—i.e., 2 lb. less than the birth weight. The infant was put to the breast three-hourly, and given a modified dried milk mixture as supplementary feeding to bring the total food up to 20 oz. per diem. On the first day the child sucked only ⅜ oz.; a further ¼ oz. was expressed from the breast, making a total of ⅝ oz. of breast-milk. On the second day the amounts respectively were ½ oz. and ½ oz.; and on the third day the total breast-milk was 2½ oz. At the end of a week the amount of breast-milk had risen to 10⅝ oz. per diem. On the twelfth day this figure had risen to 21½ oz., and on the following day mother and child were discharged, the infant being then fully breast-fed and weighing 10 lb. 9½ oz.

This surprising result was attributable to the excellent management of the case by the matron, and to the faith of the mother, who quite expected that breast-feeding would be fully established in four days.—I am, Sir, yours faithfully,

NORAH D. PINKERTON, M.B., B.S. Lond.,
Medical Officer, Chelsea Health Society.

Sept. 20th, 1927.

THE TREATMENT OF EPILEPSY.

To the Editor of THE LANCET.

SIR,—It seemed to me a pity that your comprehensive article on epilepsy did not go still further and point out how lacking are the facilities for treating case of psychogenic origin. The fact that ordinarily the general hospitals are content to act as stepping-stones in the course of the epileptic towards the workhouse makes adequate treatment often impossible. If they had psychotherapy departments, working in connexion with occupation or handicraft centres, much good might be done. The doctors and parents would know where to send these cases for early treatment, which, in the majority of instances, is more than half the battle. The epileptic colony, of course, is the ideal, but I am afraid at present it does not come within the range of practical politics.

I am, Sir, yours faithfully,

Plymouth, Sept. 20th, 1927. E. L. FOX, M.D.

ISOLATION WARDS AT LAMBETH HOSPITAL.—The lack of isolation wards at the Lambeth Hospital has again been discussed by the Lambeth Board of Guardians following the receipt of a letter from a coroner alleging delay in the removal of a diphtheria patient and who died while being transferred to the South-Western Fever Hospital. The Ministry of Health wrote expressing regret that the guardians should think of postponing, even for six months, the consideration of providing isolation wards, and a member of the board gave notice that he would move a resolution on the subject at the next meeting. The delay in securing the removal of the patient is stated to have been due to a misunderstanding on the part of the telephone operator who did not appreciate the urgency of the call.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. J. S. Austin is appointed to the Royal Hospital at Bermuda.

Surg. Lt. G. W. Garde to *Vivid*, for R.N. Hospl., Plymouth.

ROYAL ARMY MEDICAL CORPS.

Maj.-Gen. Sir M. W. O'Keeffe, K.C.M.G., C.B., retd. pay, late R.A.M.C., is apptd. Col. Comdt., vice Lt.-Gen. Sir A. Keogh, G.C.B., G.C.V.O., C.H., retd. pay, late R.A.M.C.

Capt. L. M. Rowlette to be Maj. (Prov.).

ARMY DENTAL CORPS.

Temp. Lt. D. W. N. Squires, Dental Surg., Gen. List, to be Lt.

TERRITORIAL ARMY.

Lt. W. Morrison, late R.F.A. (Spec. Res.), to be Lt.

ROYAL AIR FORCE.

J. M. Ritchie is granted a short service commission in the rank of Flying Officer for three years on the active list.

Flying Officer A. F. Cook is promoted to the rank of Flight Lieutenant.

Flying Officer M. D. Rawkins is transferred to the Reserve Class D. (ii.).

Wing Comdr. H. W. Scott to No. 21 Group Headquarters, West Drayton, for duty as Senior Medical Officer.

Squadron Leader (Dental) A. K. Macdonald to R.A.F. Depôt, Uxbridge, on appointment to a Temporary Commission.

Flight Lt. E. G. Howell to R.A.F. Depôt, Uxbridge.

Flying Officers G. T. O'Brien and Patrick O'Callaghan to Research Laboratory and Medical Officers' School of Instruction, on appointment to Short Service Commissions.

INDIAN MEDICAL SERVICE.

Lt.-Col. S. R. Christophers, C.I.E., O.B.E., to be Hon. Physician to the King, Ind. Mil. Forces, and to be Bt. Col., vice Col. C. H. Bensley, C.I.E. (retd.).

Maj.-Gen. G. Tate to be Hon. Surg. to the King, Ind. Mil. Forces, vice Maj.-Gen. R. Heard, C.I.E. (retd.).

Lts. to be Capts.: R. Linton, A.Tait, and J. F. Shepherd.

Maj. A. Seddon is transferred to the temp. non-effective list.

J. F. O. Bodman to be Lt.

DEATHS IN THE SERVICES.

Lieut.-Colonel Frederick William Wright, I.M.S. (retd.), D.S.O., who died recently at the age of 77, was born at Norwich, and was the son of Robert John Wright of that city. Educated at Bedford and at Lausanne, he graduated in medicine and surgery at the University of Edinburgh in 1872. He entered the Bengal Medical Service in 1873, and became Surgeon-Lieut.-Colonel in 1893. In the Afghan War of 1878 he was with Lord Roberts in the forced march from Kabul to Kandahar, and was present at the subsequent battle (medal with Kandahar clasp and the bronze star). Later, in 1886–87, he took part in the Burmah operations which added Upper Burmah to the Indian Empire (mentioned in despatches, medal with two clasps and the D.S.O.). He also served with the British contingent of the Expeditionary Force in China to put down the Boxer Rebellion in 1900 (medal), and in the Waziristan Campaign of 1901–02 (medal with clasp). In 1919 he was granted the Indian Army good service pension.

PRESENTATION TO DR. J. H. MARSH.—On Sept. 14th Dr. Marsh, J.P., medical officer of health for Macclesfield, was presented by his fellow practitioners with a corner cupboard and bookcase, one panel of which bears an illuminated inscription which reads as follows: "Presented to Dr. John Hedley Marsh, J.P., by the members and constituents of the County Palatine of Chester Local Medical and Panel Committees in recognition of his spirited leadership and of a decade of genial and judicious conduct in the chair." A beautiful chair also formed part of the gift, and Mrs. Marsh received a Japanese garden of miniature living trees, enclosed in an oval porcelain tray. The presentation was made by Dr. L. Grant, of Neston, Sir William Hodgson, J.P., chairman of the Cheshire County Council, presiding. Unfortunately, Dr. Marsh was prevented from being present in person owing to ill-health.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—On Fridays, Oct. 14th, 21st, and 28th, at 5 P.M., Sir Arthur Keith, F.R.S., will give demonstrations in the theatre of the College. The subjects will be: (1) Results of Recent Researches into the Reproduction and Growth of Bone; (2) Rheumatic and other Changes in Joints illustrated by specimens from the Strangeways Collection; and (3) Congenital Dislocation of the Hip and Congenital Dislocation of other Joints.

MAUDSLEY HOSPITAL.—A post-graduate course in psychiatry will be held at the Maudsley Hospital, Denmark-hill, London, S.E., during October and November. It will run concurrently with a course on Diseases of the Nervous System which is to be given at the National Hospital, Queen-square, W.C., from Oct. 3rd to Nov. 25th, and so far as possible times of lectures and demonstrations have been arranged to enable practitioners to attend both courses. Details may be had on application to the medical schools of the two hospitals.

UNIVERSITY COLLEGE HOSPITAL.—In Covent Garden Market on Wednesday last an auction and flag day was held with the object of helping to reduce the debt of University College Hospital to its bankers, £30,000 of which must be cleared off this year. Many well-known firms sent articles for the sale, and a souvenir catalogue was prepared by the Chairman of the Appeal Committee, Mrs. Joseph Gluckstein, M.B.E., J.P. Miss Melville, the leading lady at the Winter Garden Theatre, opened the sale, and Sir Alfred Butt and the directors of Drury Lane Theatre, Mr. W. G. Irving, the market superintendent for the Beecham Estates, and many leading firms in the district gave their hearty support.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The Harben lectures will be delivered in the lecture hall of the Institute, 37, Russell-square, London, W.C., on Oct. 17th, 18th, and 20th, at 4 P.M., by Prof. R. Bruynoghe, of the University of Louvain. His subjects will be the Twort-d'Herelle Phenomenon, and some New Research on Relapsing Fever.—The annual congress of the Institute for 1928 will be held at Dublin.—A course of lectures on the Health of the Nation will be given at the Institute during the next three months on Wednesdays, at 4 P.M. The programme is as follows: Oct. 12th, Sunlight for Childhood (Dr. C. W. Saleeby); Oct. 19th, Tuberculosis as a Social Disease (Prof. Lyle Cummins); Oct. 26th, Diseases conveyed to Man from Animals (Prof. F. T. G. Hobday); Nov. 2nd, Tuberculosis as a Problem of Childhood (Sir Henry Gauvain); Nov. 9th, the Present Situation in regard to Housing (Lt.-Col. F. E. Fremantle); Nov. 16th, the Milk-supply (Dr. Stenhouse Williams); Nov. 23rd, the Prevention of Heart Disease (Dr. Dingwall Fordyce); Nov. 30th, the Prevention of Cancer (Prof. Blair Bell); Dec. 7th, the Health of the Public School Boy (Dr. L. R. Lempriere); and Dec. 14th, the Changed Conditions of Quarantine (Prof. E. W. Hope).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A fortnight's course at the National Hospital for Diseases of the Heart will begin on Oct. 3rd. It will consist of lectures, demonstrations, ward rounds, and out-patient work from 10 A.M. to 4 P.M. each day and the entry is limited to 20. The Central London Throat, Nose, and Ear Hospital will hold a three weeks' course from Oct. 3rd to 22nd. It will be in two parts—clinical and operative—which may be taken separately or together. The clinical course will occupy each day from noon to 5 P.M., with operations at 9 A.M. most mornings, whilst the operative class (entry limited) will be held from 10 A.M. to 11.30 A.M. There will also be a practical course in peroral endoscopy and a course in bacteriology and pathology; the entry to these will be strictly limited. The subjects of other courses in October will be antenatal work at the Royal Free Hospital, consisting of demonstrations to not more than ten post-graduates at 5 P.M. on Fridays, Oct. 7th to 28th; diseases of children, at the Paddington Green and the Victoria Children's Hospital, morning and afternoons alternately at each hospital from Oct. 17th to 29th; electrotherapy at the Royal Free Hospital on Wednesdays at 4.15 P.M. from Oct. 12th to Nov. 2nd; gynæcology at the Chelsea Hospital from Oct. 17th to 29th; tropical medicine at the London School of Tropical Medicine on Tuesdays and Thursdays at 2 P.M. from Oct. 3rd to 29th; and a course in neurology at the National Hospital, Queen-square, from Oct. 3rd to Nov. 25th. Copies of all syllabuses and of the general course programme are obtainable from the secretary of the Fellowship at 1, Wimpole-street, London, W. 1, and will be sent regularly to those who wish it.

Dr. John Beattie, demonstrator in anatomy at University College, London, has been appointed assistant professor of anatomy at McGill University, Montreal.

ROYAL DENTAL HOSPITAL.—On Tuesday, Oct. 4th, at 4 P.M., Sir Walter Fletcher, F.R.S., will open the John Hampton Hale Research Laboratory and will distribute prizes to students. The hospital, whose address is 32, Leicester-square, London, W.C. 2, will be open to visitors from 3 o'clock.

ROYAL VETERINARY COLLEGE.—Prof. J. Macqueen, F.R.C.V.S., has been elected to the office of Dean, and Mr. Tom Hare, M.D., B.V.Sc., M.R.C.V.S., of the Lister Institute, has been appointed to the Chair of Pathology. The winter session will begin on Oct. 4th, and the opening address will be delivered at 3 P.M. on that day by Mr. E. M. Crookshank. Women students are now admitted to the College and post-graduate courses will shortly be started.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The annual dinner will be held on Wednesday, Oct. 12th, at 7 for 7.30 P.M., at the Trocadero Restaurant, Piccadilly-circus. Ladies are invited, and application should be sent to Dr. J. P. Purvis, 16, The Grove, Greenwich, S.E. 10.

BRITISH SOCIAL HYGIENE COUNCIL.—Major-General J. E. B. Seely will preside over the Imperial Social Hygiene Congress to be held at the Caxton Hall, Westminster, from Oct. 3rd to 7th. Among the speakers will be Mr. David Lees, Colonel L. W. Harrison, and Dr. H. Crichton Miller.

UNIVERSITY OF DURHAM.—Mr. R. B. Green, M.B. Lond., F.R.C.S. Eng., who for five years has held the position of lecturer in anatomy at the College of Medicine, Newcastle-on-Tyne, has been elected Professor of Anatomy in succession to Prof. R. Howden.

CITY OF LONDON HOSPITAL.—To liquidate its liabilities and carry out improvements planned as far back as 1914, at least £25,000 is needed by the City of London Hospital for Diseases of the Heart and Lungs. Though the total income last year was £34,474 and the expenditure was only £33,231, the sum of £9000 is due to the bank. The generosity of the Prudential Assurance Company has enabled the hospital to erect and equip a new pathological laboratory, but the country sanatorium at Saunderton has to remain closed for lack of funds.

DONATIONS AND BEQUESTS.—Mrs. Caroline Day, of Morley, Yorks, left £1000 each to the Women and Children's Hospital, Leeds, St. Dunstan's Hostel for the Blind, and Dr. Barnardo's Homes.—Mr. John Edwin Fyfield, High Barnet, N., on the death of his wife, left one-half of the residue of his property to endow a bed or ward in the Freemasons' Hospital, in memory of his son who was killed in the war.—Dr. John Storrs Brookfield, of Phillimore-gardens, Kensington, W., left £2000 to the University of New Brunswick, Canada, for a scholarship in natural science, and £100 each to the London Hospital, E., the Willesden Hospital, the Society for the Prevention of Cruelty to Animals, the Society for the Prevention of Cruelty to Children, and the rector of Upminster for the poor.—Mrs. Agnes Wood, of Walmer-place, Walmer, Kent, and formerly of Liverpool, besides other bequests left £5000 each to Halifax Infirmary, Royal Southern Hospital, Liverpool, Liverpool Queen Victoria District Nursing Association and Aged Merchant Seamen and Widows' Fund. In the event of the failure of certain trusts the residue falls to such charities as may be named in accordance with the provisions of the will.—Mr. Joseph Henry Farnworth, of St. Ives, Flixton, Lancashire, left £500 each to the Manchester Royal Infirmary, Ancoats Hospital, and Salford Royal Hospital and Dispensary.—Mr. George Frederick Moore, of Chardwar, Bourton-on-the-Water, Gloucestershire, left £2000 to the Bourton-on-the-Water Cottage Hospital.—The late Mr. Edwin Webster, of Birkdale, Southport, left property of the value of £35,390, with net personalty £32,591. He bequeathed real estate at Wibsey and Bradford to his wife for life, and then to the Bradford Infirmary. The residue of the property to his wife for life and then to be divided into 36 parts: Five for the Southport Infirmary, four for the London Missionary Society, three each for the Southport branch of the Society for the Prevention of Cruelty to Children and Dr. Barnardo's Homes; two each for the North of England Children's Sanatorium, Southport, the Southport Homœopathic Cottage Hospital, the Southport Hydropathic Hospital, and other charities, and one for St. Dunstan's Home for the Blind.—Mr. Thomas Hutchinson Russell, of Sowerby, nr. Thirsk, Yorks, left £1500 to the Lambert Memorial Hospital, Thirsk, and £1000 each to the Leeds General Infirmary and the Yorkshire County Hospital, York

ST. MARY'S HOSPITAL POST-GRADUATE COURSE, 1927. — This course will be held this year as usual during the week-end preceding the autumn session. On Saturday, Oct. 1st, at 11 A.M., Prof. C. A. Pannett will speak on Minor Orthopædic Problems of General Practice. The other lectures to be given on that day are as follows:—12 noon: Treatment of Pernicious Anæmia, by Sir William Willcox; 2.15 P.M.: Cæsarean Section and After, by Mr. T. G. Stevens; 3.15 P.M.: How to Deal with Retention of Urine in an Old Man, by Mr. Zachary Cope. On Sunday, Oct. 2nd, at 10.30 A.M., Dr. Ernest Young will lecture on the Use of the Duodenal Tube in Treatment of Gastric and Duodenal Ulcers; at 11 A.M. Dr. C. M. Wilson will speak on Early Recognition of Some Common Diseases; and at noon Dr. John Freeman will discuss When to Use and What to Expect from Blood Transfusion. On Monday, Oct. 3rd, at 11 A.M., Dr. Wilfred Harris will lecture on the Significance of Pain in the Lower Extremities and its Treatment. On the same day, at noon, Mr. S. Maynard Smith will lecture on Obstruction of the Large Bowel. In the afternoon lectures will be given, illustrated by lantern slides, by Mr. Aleck W. Bourne on Recent Work on the Pituitary and Ovary (2.15 P.M.), and Mr. Duncan Fitzwilliams on Early Diagnosis of Carcinoma of Tongue (3.15 P.M.). These meetings are open to all medical practitioners without fee. They will be held in the library of the Medical School, except those on Monday afternoon, which will be given in the Unit Theatre, Beverly Ward.

LORD MAYOR OF LIVERPOOL'S APPEAL.—So far the Lord Mayor of Liverpool has received £21,956 8*s.* 6*d.* in response to his appeal for £60,000 for the Liverpool medical charities.

PEOPLE'S LEAGUE OF HEALTH.—A series of ten Sims Woodhead lectures will begin on Thursday, Oct. 13th, at 6 P.M., in the lecture room of the Medical Society of London. Among the lecturers will be Prof. H. E. Roaf, Mr. E. B. Turner, Dr. J. Sim Wallace, Dr. H. Gardiner-Hill, Prof. M. S. Pembrey, F.R.S., Prof. B. Collingwood, Dr. T. Beaton, and Dr. H. Crichton Miller. Further particulars and syllabus will be supplied by Miss Olga Nethersole, 12, Stratford-place, W.

Appointments.

CAIRNS, MARGARET D., M.B., Ch.B. Edin., has been appointed Medical Officer of Health for the Burgh of Stirling.

CUFF, A. W., M.B. Camb., F.R.C.S. Eng., Consulting Surgeon to the South Yorkshire Mental Hospital, Sheffield.

JOHNSTONE, A., M.B., Ch.B. Aberd., D.P.H., Medical Officer of Health for Greenock.

JONES, L. W., M.B., B.Chir. Camb., M.R.C.S., Medical Officer and Public Vaccinator for No. 2 District of the Union in Anglesey.

PITTARD, M., M.R.C.S., L.S.A., State Medical Officer of the Island of Sark.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Jun. Asst. Ophth. S.

Ascot, Heatherwood Hospital.—Res. Asst. M.O. £300.

Belgrave Hospital for Children, Clapham-road, S.W.—H.P., Asst. H.P., and H.S. Each at rate of £100.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. At rate of £100 and £50 respectively.

Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Asst. Out-patient Reg.

Devonport, Royal Albert Hospital and Eye Infirmary.—H.S. £150.

Dundee Royal Infirmary.—Asst. S.

Durham County Council, &c.—Dist. Tub. M.O., &c. £500.

Exeter, Royal Devon and Exeter Hospital.—H.P. Also Cas. O. At rate of £130 and £100 respectively.

Freetown, Sierra Leone, Liverpool School of Tropical Medicine Laboratory.—Two Research Assts. Each £600.

Gravesend and North Kent Hospital, Kent.—Jun. H.S. £150.

Grosvenor Hospital for Women, Vincent-square, S.W.—Hon. Anæsthetist.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Anæsthetist. Also Res. M.O. and H.P. At rate of £150 and £100 respectively, and Med. Reg. £100.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each £50.

Jersey General Hospital and Poor-Law Infirmary.—Res. M.O. £200.

Jewish Health Organisation of Great Britain.—M.O. to Psychological Clinic. £1 10*s.* per session.

Kolar Gold Field Hospital, South India.—3rd Asst. M.O.

Leeds City.—Asst. Clin. Tuberculosis O. £600.

Liverpool, Mill-road Infirmary, and Smithdown-road Institution.—Res. A.M.O.'s. Each at £200.

London Hospital, E.—Asst. P. Also 1st Asst. and Reg. to one of the Med. Firms, and 1st Asst. and Reg. to one of the five Surg. Firms. Each £300.

London Temperance Hospital, Hampstead-road, N.W.—Clin. Asst., Ear, Nose and Throat Dept.

Middlesex Hospital Medical School, London, W.—2nd Demonstrator for the Dept. of Physiology.

National Dental Hospital, Great Portland-street, W.—Hon. Anæsthetist.

Newcastle-upon-Tyne Hospital for Sick Children.—Jun. H.S. At rate of £100.

Otago University and Dunedin Hospital, New Zealand.—Sen. Res. Surg. O. £500.

Paddington Green Children's Hospital, London, W.—H.P. At rate of £150.

Prince of Wales's General Hospital, Tottenham, N.—H.S.'s and H.P.'s. At rate of £120 and £90 respectively.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Two H.P.'s. Each at rate of £100.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Rotherham Hospital.—H.P. £180.

Royal Eye Hospital, St. George's-circus, Southwark, S.E.—Jun. H.S. £100.

Royal Free Hospital, Gray's Inn-road, W.C.—Cas. O. At rate of £150.

St. George's Hospital, S.W.—Asst. Radiologist. £100.

St. Mark's Hospital for Cancer, City-road, E.C.—Radiologist.

St. Mary, Islington, Infirmary, Highgate Hill, N.—Radiographer. Guinea per day.

St. Thomas's Hospital.—Asst. Pathologist in Venereal Dept.

Scottish Board of Health.—M.O. £600.

Seamen's Hospital, Albert Dock, Connaught-road, E.—Ophthalmologist.

Shrewsbury, Royal Salop Infirmary.—Sec. Supt. £600.

Smethwick County Borough.—Asst. M.O. and Sch. M.O. £600.

Stoke-on-Trent, North Staffordshire Royal Infirmary, Hartshill.—Hon. Asst. Ophth. S.

Sudan Government, Wellcome Tropical Research Laboratories, Khartoum.—Asst. Bacteriologist. £E.720.

Warwickshire and Coventry Joint Committee for Tuberculosis.—Asst. Tuberculosis O. £650.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Non.-Res. H.S.'s. At rate of £150 and £100 respectively.

Willesden General Hospital.—H.S. At rate of £100.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Cardenden (Fifeshire), Festiniog (Merionethshire), Ripon (York, West Riding), St. Mary's (Isles of Scilly), Breage (Cornwall), and Beith (Ayrshire).

Births, Marriages, and Deaths.

BIRTHS.

BHANDARI.—On Sept. 15th, at "Old Court," Hanger-lane, Ealing, the wife of Dr. P. C. Bhandari, of Brentford, of a daughter.

BUCKLEY.—On Sept. 15th, at Kensington, the wife of Major C. D. M. Buckley, *M.C.*, R.A.M.C., of a son.

STUART.—On Sept. 14th, at Lowestoft, the wife of Surg.-Lieut. A. P. Anderson Stuart, R.N., of a daughter.

MARRIAGES.

BOWLES—GREAVES.—On Sept. 19th, at St. Stephen's Church, Rosslyn-hill, N.W., Roger Vincent Bowles, M.R.C.S., L.R.C.P., to Florence Maud Evelyn Greaves, elder daughter of Mr. and Mrs. Edwin L. Greaves, of Keats Grove, Hampstead, N.W.

LYDON—ANDERSON.—On Sept. 15th, at Sheffield, Francis L. Lydon, M.B., Ch.B., of Galway, to Helen Anderson, M.B., Ch.B., of Galway.

ORR—BENTALL.—On Sept. 15th, at Chapel-street Congregational Church, Southport, Ian Morison Orr, M.B., Ch.B., to Marjorie Violet, daughter of W. C. Bentall, O.B.E., F.R.C.S.E., and Mrs. Bentall, Oxford-road, Birkdale, Lancs.

PARRY—GRIFFITHS.—On Sept. 13th, at Tredegarville Baptist Church, Owen Brynog Parry, M.B., B.S. Lond., of Ninian-road, Cardiff, to Constance Lilian Griffiths, M.B., Ch.B., B.Sc., of Richmond-road, Cardiff.

DEATHS.

BREWER.—On Sept. 7th, at Fairview-road, Oxton, Birkenhead, Dr. Charles Samuel Brewer, O.B.E.

GAMGEE.—On the 16th inst. at Folkestone, Margaret, the dearly loved wife of Leonard Gamgee, F.R.C.S., 5, Norfolk-road, Edgbaston, Birmingham.

HARDWICK.—On Sept. 13th, at Richmond, Yorkshire, Harold George Cooke Hardwick, B.Chir. Camb., M.R.C.S., L.R.C.P., aged 64.

WRIGHT.—On Sept. 9th, suddenly, at Bournemouth, Lieut.-Colonel Frederick William Wright, D.S.O., I.M.S. (retd.), of Cromwell-road, South Kensington, aged 77.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE BIRTH OF MANKIND.

THE history of books which have had an influence upon knowledge is always interesting, particularly when we can trace the life of a book from its birth, throughout its life until its supersession or practical death. Such a pedigree is extant in the case of a book which had an enormous popularity in its day—namely, "The Birth of Mankind," or "The Woman's Book," the bibliography of which has been set forth at length by Sir D'Arcy Power in a paper read before the Bibliographical Society and which is now printed from the Transactions of the Society by the Oxford University Press. "The Woman's Book" first saw the light in 1513, when the Emperor Maximilian granted it copyright. The author was Eucharius Rosslin, city physician of Worms, and the original title was "Der Swangern Frauwen und Hebammen Roszgarten"—hence it has been colloquially known as "the Rosegarden." There was nothing particularly original in the book—it was an illustrated manual of midwifery compiled from ancient sources and mainly from Muscio's Latin version of Soranus's treatise on midwifery. Rosslin had an immediate success as an author, and his work was translated into Dutch in 1516, into Czech in 1519, into French in 1536, into Latin in 1532, and into English from the Latin in 1540, this version being the earliest known work in the English tongue on midwifery. The English translator was one Richard Jonas, of whom practically nothing else is known, and he dedicated his labours to "the most excellent vertuous Lady Quene Katheryne wyfe and most derely belouyd spouse unto the moste myghty sapient Christen prynce King Henry the VIII." It is a sad comment upon the vanity of human affairs to remember that two years later the head of the most excellent virtuous Lady Catherine Howard was cut off in the Tower by command of the most mighty Christian prince. In 1545 a new edition appeared enlarged and edited by Thomas Raynoldes, whose name appears on the title page of every successive edition until the last, that of 1654. There seems some doubt as to who he was, but he describes himself on the title page of the 1545 edition as "phisition." Sir D'Arcy Power takes his readers through the various editions and gives full bibliographical details of them and also reproduces many of the title pages. He also gives biographical particulars of the various printers and publishers. Thomas Adams, who published the 1604 and 1613 editions, was the son of a yeoman of Nyensavage, in Shropshire, a place which Sir D'Arcy Power cannot identify; there are two villages of the name "Neen" as now spelled, in Shropshire—namely, Neen Savage and Neen Solars, respectively east and south-east of Ludlow.

Other information about the book, not only bibliographical, appeared in THE LANCET for Nov. 22nd, 1924, in the Lloyd Roberts' Lecture delivered by Dr. Herbert Spencer.

TINEA CRURIS.

To the August number of the *Indian Medical Gazette* Lieut.-Colonel H. W. Acton and Dr. C. McGuire contribute a scholarly paper on Tinea Cruris, its Manifestations, Diagnosis, and Treatment, which covers a much wider field than its modest title suggests. It is a mistake, as they point out, to suppose that the ravages of the fungus responsible for dhobie itch are confined to the groin, for they are just as common on the feet and perhaps on the hands as well. This fact has been recognised by dermatologists for some time past, and the diagnosis of "gouty eczema" of the feet is a great deal less common than it used to be. In India eczematoid ringworm of the extremities and ringworm of the groin are often seen both in Europeans and Indians of all classes. Colonel Acton and Dr. McGuire believe that both forms are caused by the same fungus, *Epidermophyton inguinale*, which they also regard as responsible for many cases of cheiropompholyx. Moisture, heat, and friction are rightly considered predisposing and aggravating causes, and there is much to be said for the statement that many persons with no obvious sign of infection carry the nidus of it about with them in the interdigital space between the fourth and fifth toes, where it may lie dormant during residence at a hill station or in a temperate climate until the heat of the plains causes it to flare up again. The same sequence of events has often been noted in this country.

Several excellent photographs illustrate some of the clinical types of the disease, which are discussed in detail in the text, together with their common pyogenic complications. The mycology, methods of cultivation, and morphology are carefully recorded and illustrated by half-tone and coloured pictures. The histopathology, which explains the clinical types of the various lesions, is methodically examined, whilst the comments on treatment and prophylaxis will be useful to all who come across the protean manifestations of this troublesome infection.

THE TREATMENT OF DRUG ADDICTS IN PRISON.

A DRUG addict, against whom there were no previous convictions, was sentenced at Marlborough-street police-court on Sept. 17th to three months hard labour on each of four charges of obtaining money by false pretences with intent to defraud. Mr. Mead, the police-court magistrate, wisely made these terms of imprisonment consecutive and not concurrent, observing that it was quite possible that a year's imprisonment might effect a cure of the drug habit. He also stated that he appreciated that the sudden cessation of the drug might be serious for the defendant, and he would therefore draw attention on the commitment to the question whether it might not be considered necessary for the accused, subject to medical orders, to have discreet doses. But this, surely, is a question which may safely be left to the unfettered discretion of the medical officer of the prison, provided that the latter is fully informed (as he should be) of the history of the case. Judicial assistance in the prescription of medical treatment seems as unnecessary in the case of morphia addiction as it would be in the case of delirium tremens; moreover, the medical officer of a prison, administering a drug in the course of the proper treatment of a prisoner, requires no protection from the penal sections of the Dangerous Drugs Acts. The treatment of drug addicts in prison has presumably not yet necessitated any general instructions; the latest annual report of the Prisons Commissioners is silent on the subject. Nor is it known whether the Home Office has addressed any circular to magistrates to emphasise the value of a longer rather than a shorter sentence in such cases.

In the recent proceedings at Marlborough-street the accused was described as independent and his age was given as 42. He had served in the army in 1914 with credit and had relinquished his commission in 1915 on account of ill-health. He was stated to have been bankrupt four times. His offences were those of defrauding tradespeople by worthless cheques for small amounts. He informed the police that he had been ill for five years, was a drug-taker, and had been under the care of two doctors. A detective-sergeant from New Scotland Yard said that one of the doctors had been interviewed and had stated that the accused had been a drug addict for several years; he would still require treatment and his supply of morphia should be cut down gradually. A medical certificate was put in to the effect that the defendant had been a drug addict for years and that this condition had in all probability affected his moral sense. There seems to have been no suggestion of the accused obtaining supplies of morphia concurrently from more than one practitioner; indeed, the circumstances of the case did not involve reference to the Dangerous Drugs Acts or Regulations. The accused pleaded "Guilty" to the charges, and the task before the court was to decide the best means of protecting the community from the accused and protecting the accused from himself.

THE STANDING NURSE.

[To the Editor of THE LANCET.

SIR,—I feel sure there is no foundation for the charge contained in Dr. T. F. G. Mayer's letter on this subject in THE LANCET of Sept. 17th (p. 636). In hospitals the health of the nurses is carefully considered and they are encouraged to sit at their work when possible. It is the rule for nurses to sit when giving light treatment. In all the nursing homes I know the nurses are certainly not required to stand unnecessarily. I cannot imagine any nurse being so stupid as to stand when giving prolonged treatment which can be efficiently carried out when seated. It must be so uncomfortable for the patient!

Nurses must be getting rather tired of other people "taking up the cudgel" on their behalf. Most of them are modern girls and are quite capable of looking after themselves. There is very little unemployment amongst them, and if a nurse finds her condition of work intolerable she is practically certain of being able to obtain another post. The only people who may have difficulty in finding employment are the elderly, unfit, and the partially trained.

I am, Sir, yours faithfully,

Sept. 20th, 1927. MATRON.

To the Editor of THE LANCET.

SIR,—It was with great interest that I read Dr. Mayer's letter in your last issue calling attention to the often very unnecessary standing by nurses in carrying out medical or nursing treatment. As a practical nurse and one holding authority for many years, I have found it impossible to ignore the fact that this matter calls for serious attention if efficiency of the worker is to be maintained. I am in close touch with many of my colleagues of older years who are

debarred from many forms of exercise entirely owing to varicose veins developed and "neglected" during their training.

If only some of the scientific management and intelligent care of the employees applied by leading industrialists could be brought to bear in hospitals, the result would be a healthier body of workers and a much more efficient service. One does not wish to overlook the fact that in a busy ward of a hospital the demands of many patients allow of practically no time whatever for sitting, also that continued practice in standing enables us to stand the strain better than many who have chosen other walks in life; but it is wasteful, unintelligent, and shortsighted to stand, if the same degree of efficiency can be attained by sitting. Many nurses fear to sit lest their patients should think they were relaxing unnecessarily, for many patients feel they are not being nursed unless the nurse is unceasingly active, quite forgetting the strain of responsibility and certain tension of mind the nurse is always aware of in connexion with her patient.

It would be a great help if in giving direction to a nurse, the medical man would indicate that certain treatment could be carried out while the nurse was sitting. This would reassure the patient that there was no negligence and would also "train" the nurse to husband her strength, a training which up to now has not been emphasised in our schools.

I am, Sir, yours faithfully,

Sept. 20th, 1927. PUBLIC HEALTH NURSE.

THE SHIPPING EXHIBITION AT OLYMPIA.

AT the Shipping Exhibition that opened at Olympia on Sept. 8th and continued for a fortnight there were fewer exhibits of interest to the seafaring hygienist than there were last year. There were two fans with "runners" like the well-known Sirocco—namely, the Capell (on the same axle as its driving steam turbine) and the Mawdsley (electric driven). Messrs. Siebe and Gorman had a diving exhibit and showed several patterns of outfit for men who have to work in dangerous gases or in fire. There was a model of a diver who carries with him the air for his own breathing, so that he has not to bother with a pump or that further cause of anxiety, an air-pipe. He cannot, of course, work for long spells or at great depths, but could leave a submarine, if she were checked at ten fathoms or less, and seek for the obstruction, re-entering the water-lock through which he had left the boat. This lock being then closed to the sea and freed from water by compressed air, the diver would be gradually decompressed according to the rules and received back among the crew. This firm showed also a glass-sided tank in which a diver gave exhibitions of cutting iron, under water, with the oxy-acetylene blowpipe.

THE ACTION OF LIQUID PARAFFIN ON THE BOWEL.

IN order to decide what is the action of liquid paraffin upon the fæces Dr. E. Schlagintweit, of Munich, has undertaken a series of experiments on white mice, and describes them in the *Münchener Medizinische Wochenschrift* of April 22nd. Paraffin, when introduced into the stomach in whatever quantity, took four to five hours to appear in the excreta, and its excretion went on for a length of time varying with the dosage; this was seven hours for a dose of 0·001 c.cm. per gramme of body-weight, which roughly corresponds to the dose usually prescribed in man. The normal interval between ingestion of food and its excretion was ascertained to be five to six hours, and a dose of paraffin reduced this to four to five hours, a fact which shows that paraffin is definitely a laxative. The theory that it acted as a lubricant between the intestinal wall and the fæcal column was not supported by actual inspection. Sections from the stomach and all parts of the bowel showed the paraffin emulsified extremely finely throughout the whole fæcal mass; never in its whole transit did it form a confluent surface. Only when massive doses were given did it escape as a liquid from the anus. Paraffin, though difficult to emulsify in water, divides readily enough when mixed with digestive secretions, and this is the causes of its immediate emulsification in the stomach. Paraffin softens the end of the column and is, therefore, therapeutically effective, says Dr. Schlagintweit, but its softening action is due not to its lubricating, or even its emulsifying properties, but to its power of holding water in emulsified form. Stools that contain paraffin contain also 15 per cent. more water than usual, and water in this state is very resistant to absorption by the bowel. He prefers emulsified paraffin to the pure oil, on the ground that a ready-made emulsion does not leak in overdose. Dr. Schlagintweit's results, although they cannot be transferred without due reserve to human experience, may yet serve to provoke further inquiry into the mechanism of so-called intestinal lubricants.

HYPOTENSION OF AMERICANS IN PEKING.

IN the current issue of *Archives of Internal Medicine*, Dr. C. L. Tung comments on the fact that in examining groups of healthy Chinese the average blood pressure, both systolic and diastolic, is lower than that of Occidental races. The average systolic pressure of healthy adults in the United States is approximately 125 and the diastolic 80. For Chinese of the same age the pressures are 112 and 70 respectively.

These facts have led him to study the effects on blood pressure of residence in Peking, in 58 Americans. Readings were taken in America and again in Peking after three years there. The readings showed a decrease in both systolic and diastolic pressure in over 60 per cent. and an increase in only 15 per cent. There was an average decrease of 9 mm. of mercury in systolic, and 11 mm. in diastolic, pressure, in spite of the increase of age. Dr. Tung points out that the fall of pressure cannot be due to climatic changes, for Peking is in the temperate zone, but suggests that the quieter life there, as opposed to the rush of American life, may be the cause. More details about the occupation and mode of life of each individual might help to solve this problem.

METROPOLITAN HOSPITAL NURSES' HOME.

WE are asked to say that the nurses' home which the Metropolitan Hospital proposes to build at a cost of £60,000 will accommodate 114 members of the nursing staff together with the necessary study and recreation rooms and not only 60 nurses and six sisters as previously stated.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 26th, to SATURDAY, Oct. 1st.—WESTMINSTER HOSPITAL, S.W. Course in Medicine, Surgery, and the Specialties. All day course from 10.30 A.M. to 5.30 P.M. Lectures, demonstrations, and operations.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, Great Portland-street, W. Course in Orthopædics. All day, operations in the morning, followed by clinical demonstrations and clinical work in the afternoons.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, W. Course in Ophthalmology. Afternoons only. Clinical demonstrations at 2 P.M. followed by operations. Special demonstrations at 5 P.M.—BETHLEM ROYAL HOSPITAL, St. George's-fields, S.W. Psychological Medicine, Tuesdays and Saturdays at 11 A.M. Further information from Secretary, Mayfair 2236.

WEST LONDON HOSPITAL, POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Sept. 26th.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Donald Armour: Operations.

TUESDAY.—10 A.M., Medical Registrar: Ward Demonstration. 2 P.M., Mr. Sinclair: Surgical Out-patients. 3 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseases of Children. 2 P.M., Mr. Gibb: Eye Department.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Ironside: Medical Out-patients. 3 P.M., Mr. Simmonds: Surgical Out-patients.

FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Addison: Operations. Mr. Vlasto: Throat, Nose and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy and Ward List. 10 A.M., Dr. Owen: Medical Diseases of Children.

Operations, Medical, Surgical, and Special Out-patients, daily, 10 A.M. to 5 P.M.; Saturdays, 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Sept. 26th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Sept. 27th.—4.15 P.M., Dr. J. C. Bramwell: Dyspnœa.

FRIDAY.—4.15 P.M., Dr. K. B. Pinson: Anæsthetics: When not to use Chloroform.

VALENTINE'S PREPARATION
NUTRIO PER ME
VOLUME 1⅘ OZ.
MEAT JUICE
The result of an Original Process of preparing Meat and extracting its Juice by which the elements of nutrition are obtained in a State ready for immediate absorption.
DIRECTIONS. Dissolve one teaspoonful of the Preparation in three tablespoonfuls of cold or warm water. Boiling water changes the character of the preparation.

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach, Aiding Digestion** and **Sustaining** and **Strengthening, Valentine's Meat-Juice** is employed in **Hospital** and **Private Practice** in the treatment of

Diseases of Children.

Dr. Raphael Raimondi, *Consulting Physician of the Montmartre Nurseries, Paris, France:* "I use VALENTINE'S MEAT-JUICE with Nurslings eighteen months to two years old. These very Weak Babies derive great benefit from the use of this tonic preparation. I give it to Debilitated Infants, after they are eighteen months old, in doses of one teaspoonful in thirty grammes of boiled water twice a day, and to be continued for a month."

Park B. Tucker, M. D., *Health Officer, Hamilton, Bermuda:* "I have found VALENTINE'S MEAT-JUICE invaluable for teething children, who readily take and retain it when they refuse everything else. It has also proved very palatable and strengthening in all cases of irritable stomach, especially to that peculiar nausea so often complained of from the abuse of ardent spirits."

For Sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
RICHMOND, VIRGINIA, U. S. A.

STEVENS' PRACTICE OF MEDICINE

New (2nd) Edition

The advances that have been made in Internal Medicine since the appearance of the first edition of this work have necessitated important changes in the text. To bring the book as nearly as possible up to date many deletions have been made and much new matter has been added. The articles dealing with syphilis of the circulatory system, botulism, heliotherapy, diabetes mellitus, alkalosis, spasm of the œsophagus, chronic ulcerative colitis, multiple polyposis of the intestine, jaundice, bradycardia, paroxysmal tachycardia, arterial hypotension, primary purpura hæmorrhagica, erythræmia, hæmorrhagic diseases of the newborn, trigeminal neuralgia, and tumours of the cauda equina have been rewritten. Reference to the following subjects appears for the first time: Primary meningococcic bacteriæmia, disseminated erythematous lupus, tularamia, epidemic jaundice, etiology of scarlet fever, Dick test for determining susceptibility to scarlet fever, coccidoidal granuloma, lipodystrophy, agranulocytic angina, uveoparotid fever, vasomotor rhinitis, occlusion of the coronary arteries, melanuria, Epstein's nephrosis, sickle cell anæmia, Ayerza's disease, chronic sclerosing osteitis, acrodynia and Horner's syndrome. Minor changes and elaborations occur on almost every page.

"Dr. Stevens has succeeded in giving a succinct presentation of the various internal diseases, and in these days of increasing specialisation owing to the rapid advance of medical science on all fronts, this is no light task. His book is well adapted to the needs of the student and general practitioner. Numerous references are quoted, and wherever we have sampled its voluminous contents and checked the references given in Dr. Stevens's work, we have found evidence of a wide and accurate knowledge of recent medical literature and a wealth of clinical experience."—BRITISH MEDICAL JOURNAL.

By A. A. STEVENS, A.M., M.D., Professor of Applied Therapeutics in the University of Pennsylvania. Octavo of 1,174 pages. Cloth, **35s.** net.

Mallory and Wright's Pathological Technique

By F. B. MALLORY, M.D., and J. H. WRIGHT, M.D., of Boston. Eighth Edition. Octavo of 666 pages, with 180 illustrations. Cloth, **32s. 6d.** net.

"Has long been a popular book with laboratory workers. First issued in 1897, it has grown with the times. An almost indispensable book of reference."—BRIT. MED. JOUR.

de Schweinitz's Diseases of the Eye

By G. E. de SCHWEINITZ, M.D., Professor of Ophthalmology, University of Pennsylvania. Octavo of 832 pages, 415 text illustrations, and 6 chromo-lithographic plates. Cloth, **50s.** net.

"We have no hesitation in saying that de Schweinitz's "Diseases of the Eye" is one of the best handbooks in our language on its subject."—BRITISH MEDICAL JOURNAL.

Jordan's General Bacteriology

By E. O. JORDAN, Ph.D., Professor of Bacteriology, University of Chicago. Eighth Edition. Octavo of 752 pages, illustrated. Cloth, **25s.** net.

"The lucidity and systematic arrangement make it very suitable as a general introduction to bacteriology."—LANCET.

De Lee's Obstetrics

By JOSEPH B. De LEE, M.D., Professor of Obstetrics, Northwestern University Medical School, Chicago. Fourth Edition. Large octavo of 1123 pages, with 1128 illustrations, 201 in colours. Cloth, **55s.** net.

"We can confidently recommend it alike to the student and practitioner."—EDINBURGH MEDICAL JOURNAL.

Da Costa's Modern Surgery General and Operative

By J. CHALMERS DA COSTA, M.D., Professor of Surgery, Jefferson Medical College, Philadelphia. Ninth Edition. Octavo of 1527 pages, with 1200 illustrations, some in colours. Cloth, **45s.** net.

"Wide and discriminate reading, evincing the most ample knowledge of the literature of his subject, a scrupulous fairness in appraising other men's ideas and methods, a transparent honesty, and complete absence of dogmatism, are the most attractive features of this book."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

Stevens' Text-book of Therapeutics

By A. A. STEVENS, A.M., M.D., Professor of Therapeutics, University of Pennsylvania. Octavo of 793 pages. Sixth Edition. Cloth, **30s.** net.

"... at once comprehensive, up to date, and discriminating, it is one of the best we have met."—LANCET.

W. B. SAUNDERS COMPANY, Ltd., 9, Henrietta Street, LONDON, W.C. 2.

THE MUSEUM GALLERIES

Telephone : Gerrard 3932 (STUDIOS) *Telegrams : Museumgal*

53, SHORT'S GARDENS, DRURY LANE, LONDON, W.C. 2

have pleasure in announcing to their numerous supporters the forthcoming issue of engravings in pure mezzotint by Mr. SCOTT BRIDGWATER, of the great Master, Corot, the first of which will be :

"*The Bent Tree*"

the original of which is in the National Gallery,

and the second will be :

"*Macbeth and the Witches*"

the original of which is in the Wallace Collection.

The titles of the others will be announced later.

The Museum Galleries also have pleasure in announcing a series of engravings by Mr. ARTHUR HOGG of those wonderful paintings by Gabriel Metsu in the Wallace Collection. The first of which will be :

"*The Sleeping Sportsman*"

THE MUSEUM GALLERIES also wish to remind those of their subscribers who were unable to visit their stand at the British Medical Association's Exhibition at Edinburgh that they will be very happy to see them at their Studios, at the above address, where they will be able to see work in progress of the above-mentioned engravings, failing which they will be pleased to send illustrated prospectuses of the work as soon as ready on receipt of the filled-in form attached.

To THE MUSEUM GALLERIES (Studios),
53, Short's Gardens, Drury Lane,
London, W.C.2.

Gentlemen,—Please send me full particulars of your issues, gratis.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY.

By HAMILTON BAILEY, F.R.C.S. (Eng.),

Surgeon, Dudley Road Hospital, Birmingham.

The History and Physical Methods of Examination must always remain the main channels by which a diagnosis is made. The pages of this book show the methods in pictorial form, and are the outcome of a series of demonstrations on the elicitation of physical signs, which was commenced at the Liverpool Royal Infirmary in 1921, and later continued at the London Hospital.

Ninth Edition. Fully Revised. With 343 Text Illustrations and 14 Plates. Demy 8vo. 634 pp. **21s.** *net; postage 9d.*

The British Car of Aircraft Quality

AIRCRAFT quality means the power to go on and on without fatigue or failure. To carry on at high pressure without tiring the engine, to subject the car to the severest trials and know that it will survive.

It is the Aircraft quality bred in the Armstrong Siddeley chassis that accounts for its wonderful reputation for reliability.

ARMSTRONG SIDDELEY

INVALID FURNITURE

Telephone: Langham 1040.

By Appointment

RESTING in an ordinary armchair is a kind of stationary obstacle race. First you've to get a footstool—and it's sure to be just the wrong height; then there's a cushion to be gingerly inserted behind your head, which promptly drops out the moment you reach for your book . . . and then you get up and begin all over again.

That's when a Carter Chair is wanted—perfectly and instantaneously adjustable to *any* restful position.

Reclining Chairs, Self-propelling Chairs, Bath Chairs, Hand Tricycles, Bed-tables—particulars of these and every other kind of Invalid Furniture will be readily sent on request.

125, 127, 129, GREAT PORTLAND STREET, LONDON, W.1.

THE

London Medical Exhibition

(Established 1905)

THE CENTRAL HALL, WESTMINSTER, S.W.

Monday, Tuesday, Wednesday, Thursday and Friday, October 3, 4, 5, 6 and 7, 1927.

From 12 noon till 6.30 p.m. Daily.

Organised by the Management of the Exhibition of the 17th International Congress of Medicine, 1913, and of the Fifth Clinical Congress of Surgeons, 1914.

THE ANNUAL DISPLAY
OF THE
LATEST ADAPTATIONS OF RESEARCH.

EVERY CLASS OF AID TO MEDICAL AND SURGICAL TREATMENT.

THE LARGEST EXHIBITION YET HELD.

STRICTLY CONFINED TO THE PROFESSION.

A Handsome Reception Room.
Orchestra.

A Spacious Tea Room.
Light Refreshments.

Invitation cards will be sent to every member of the Profession residing in London and in Counties within 100 miles of the Metropolis. Practitioners desiring to visit the Exhibition who do not receive cards can obtain same on application to the Secretary, the London Medical Exhibition, 194-200, Bishopsgate, London, E.C., or at the Central Hall during the Exhibition week.

PRESS OPINIONS.

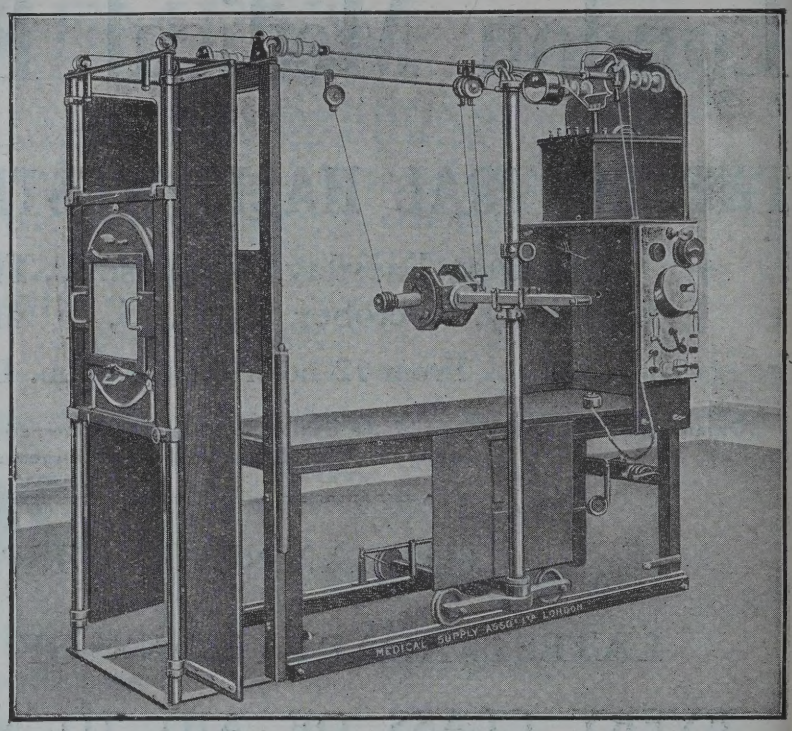
"THE LANCET."

A most informative collection of drugs and appliances used in the art of medicine and surgery, organo-therapeutic, bacteriological and pharmaceutical remedies, electro-therapeutic apparatus, and many ancillary agencies, such as dietetics, and hospital and invalid furniture, were displayed. The medical man is essentially a student, but in these days progress is so rapid that even the attendance at post-graduate courses hardy suffices to keep the practitioner abreast of present-day treatment. An exhibition of this kind affords an opportunity to the busy practitioner to see the products and inventions which follow so closely on advances in treatment or technique, and to appreciate the labours of the various firms who, in response to the scientific requirements necessitated by research, administer to the needs of medicine and surgery. That the exhibition really fills a need is shown by the large number of medical men who visited it between the hours of noon and 6.30 p.m. each day, and by the keen interest which they took in the exhibits. In addition, the exhibition afforded an opportunity for friendly discussion and social intercourse, for which arrangements were made by the organisers, while the presence of many foreign and overseas visitors, some 300 of the latter having applied for tickets, showed the wide appeal of this display of scientific medicine and surgery.

"THE MEDICAL PRESS and CIRCULAR."

The attendance, which was exceedingly good, was confined to the medical profession, the general public not being admitted, and several thousands of medical men from all parts of the Kingdom found ample to interest them in the displays made by the leading firms. The Exhibition, year by year, has become more professional. It was noticeable on this occasion that the exhibits demanded more than one visit from many members of the medical profession, and there can be little doubt from the repeat inspections that practitioners found many of the demonstrations not only interesting and educational, but of immediate application in practice.

"The Outfit that Simplifies Radiography."



The N.P.L.

UNIVERSAL X-RAY APPARATUS

THE CERTIFICATED APPARATUS.

This apparatus is exactly what its name implies—a *universal* X-Ray Apparatus. It provides for radiography (general, dental, compression); radiotherapy; horizontal screening; vertical screening. It is the ideal all-round X-ray equipment for hospital, clinic, or private practice.

THE UNIQUE TECHNIQUE DIRECTOR has revolutionised radiography. By the turning of a knob it gives automatically every factor required for producing successful radiograms with certainty. These factors obtained, the setting of the controls is the essence of simplicity.

THE N.P.L. APPARATUS GIVES FULL PROTECTION. It is unconditionally certificated by the National Physical Laboratory as complying with the recommendations of the X-Ray and Radium Protection Committee.

The N.P.L. Universal X-Ray Apparatus is extremely compact. It occupies a floor space of only 7ft. 6in. × 2ft. 8in.

Price, complete with all Accessories for Alternating Current - - £300

" " " " Direct Current - - - £345

Being entirely of British manufacture, this apparatus is free of importation duty.

Hundreds of N.P.L. Outfits in daily use.

CALL AND SEE THE APPARATUS AT WORK. YOU WILL DELIGHT IN ITS EFFICIENT SIMPLICITY. OR LET US SEND YOU SPECIMEN RADIOGRAMS AND CATALOGUE L26.

A Nutrient of Wide Utility

IN HORLICK'S MALTED MILK full-cream dairy milk is combined with and modified by the soluble derivatives of malted barley and wheat, presenting a well-balanced, partially predigested invalid food of marked restorative qualities which is easily assimilable and very rapidly absorbed. It has a high vitamin content, is bland and soothing, and satisfactorily solves the question of a proper diet in Gastro-intestinal disorders, Nephritis, Typhoid Fever, Pneumonia, Cardiac diseases, and other morbid conditions of the system. As a post-anæsthetic diet Horlick's is invaluable and it is also an efficient Nutrient Enema.

To secure the original, always specify HORLICK'S.

HORLICK'S THE ORIGINAL MALTED MILK

Made in England by

HORLICK'S MALTED MILK CO., LTD., SLOUGH, BUCKS.

Liberal samples free to Members of the Profession.

To take the place of Meat

It is often undesirable that a patient should take meat.

In such cases an alternative diet often presents difficulty.

Kraft Cheese, by reason of its constituents of casein, butter fat, minerals, and vitamins, forms an excellent basis of a meatless diet.

Kraft Cheese has a far higher nutritive value than prime beef, and its low acid content makes for easy digestion.

It is recommended by the highest dietetic authorities.

All genuine Kraft Cheese bears this trade mark:

KRAFT K CHEESE

TRADE MARK REGISTERED

Sold by weight, and in 1 lb. and ½ lb. Cartons and Kraftet portions.

Also Kraft "Imperial" and Kraft "Valveta."

KRAFT-MacLAREN CHEESE CO., Ltd. (Montreal, Canada), HAYES, MIDDLESEX.

VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, nor cumulative in action, and in ordinary cases of insomnia one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anæsthesia is produced, and as a result much less of the anæsthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used more safely than other hypnotics when the heart is weak. Where sleeplessness is a concomitant of pain, rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELIXIR ACID. ACETO-SALICYLIC (Hewlett's).

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN. Price **10/6** per lb.

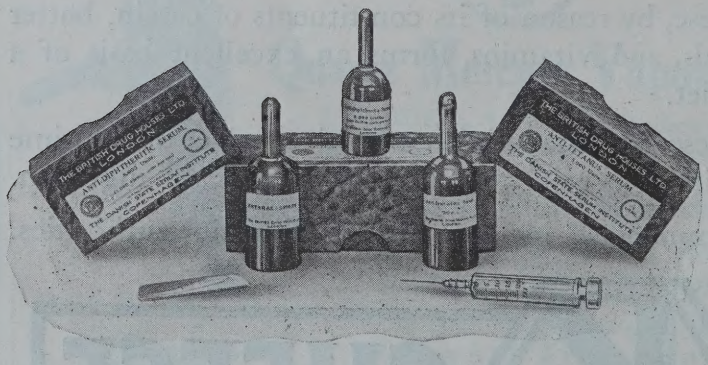
ANTI-DIPHTHERITIC SERUM

(Diphtheria Antitoxin)

D. S. I. BRAND

For Prevention and Treatment



It is now established that in those districts where immunization with D.S.I. Anti-Diphtheritic Serum is practised diphtheria is rarely met with, and then in a very mild form only. Further, it has been proved that in hospitals in which D.S.I. Anti-Diphtheritic Serum is used exclusively for the treatment of faucial diphtheria, 99 per cent. of the cases recover.

The reason for this is that Anti-Diphtheritic Serum D.S.I. Brand is of the highest potency. It is prepared at its greatest strengths by natural means, concentration by artificial means being unnecessary.

Anti-Diphtheritic Serum D.S.I. Brand is not only highly concentrated, but it is exceedingly rapid in action—hence its value in the treatment of a disease where time is such an important factor.

Literature and full particulars of prices of all D.S.I. Vaccines and Sera are obtainable from the

ALOCOL

Colloidal Hydroxide of Aluminium

Successful Treatment of Hyperchlorhydria

"Alocol" is a triumph of colloidal therapy because it is completely free from the marked disadvantages associated with the usual alkaline medicaments.

Take bicarbonate of soda as an example. When in the stomach it is transformed into sodium chloride—the very product which goes to the formation of hydrochloric acid. To combat hyperacidity by such means is to create a vicious circle.

Note the different action of "Alocol." It absorbs excess of hydrochloric acid and the acid-containing mass is finally evacuated from the lower bowel. This colloido-chemical absorption removes from the system the causative acid radicle (Cl) instead of merely neutralising it.

"Alocol" thus prevents reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

"Alocol" leaves intact the acid reaction of the gastric juice and its normal digestive and bactericidal functions. It is the remedy *par excellence* for hyperchlorhydria. The absorbent, healing and sedative properties of "Alocol" also prove of the greatest value in successful treatment of the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, infective enteritis, &c.

Complete chemical history of "Alocol" with convincing clinical reports, and supply for trial, sent free to physicians on request.

BOOTS PRODUCTS

ACRIFLAVINE (BOOTS)

ONE of the most potent of modern antiseptics, Acriflavine-Boots is guaranteed physiologically pure and extremely soluble in water. Acriflavine-Boots kills organisms in a concentration of 1 in 100,000. Its potency is actually increased when brought into contact with serum. Acriflavine-Boots is now recognised as the routine preparation for irrigations in the treatment of Gonorrhœa. It is ideal for suppurating wounds and septic conditions of all kinds.

Acriflavine-Boots is supplied in 5 gm. and 20 gm. bottles, and in tablets (1.75 gr. and 2.187 gr.).

Neutral-Acriflavine-Boots is specially prepared for internal use in the form of enteric-coated tablets, and also for hypodermic and intravenous injections.

Neutral-Acriflavine-Boots is supplied in 5 gm. and 20 gm. bottles, in tablets (1.75 gr.), and enteric-coated tablets ($\frac{1}{2}$ gr.).

Vitamins

WATER-SOLUBLE and fat-soluble vitamins are presented in therapeutically active form in Metagen and Cod-Liver Oil Emulsion (P., D. & Co.). The Cod-Liver Oil used in this emulsion is specially selected on account of its high vitamin content which is verified by physiological tests, and it is reinforced by the addition of the water-soluble vitamins of Metagen.

A deficiency of vitamins has been shown to predispose to many infectious diseases occurring in adult-life, as well as to rickets, dental caries, marasmus and other disorders of childhood.

Not only the fat-soluble, but also the water-soluble vitamins must be supplied in adequate amounts in order to maintain bodily processes in healthy activity and to promote general health and well-being. Metagen and Cod-Liver Oil Emulsion contains these vitamins in a palatable form, ready for immediate assimilation.

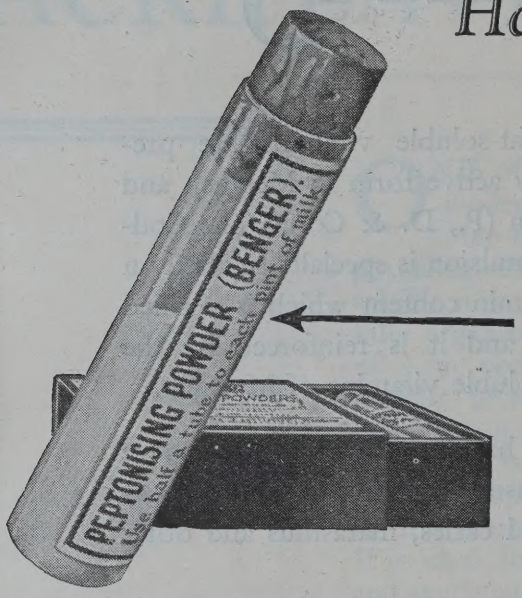
Metagen and Cod-Liver Oil Emulsion

Supplied in bottles of 8 *and* 16 *fluid ounces.*
A specimen will be supplied to any physician on request.

PARKE, DAVIS & COMPANY, 50, BEAK ST., LONDON, W.1.

The most efficient Peptonising Powders!

Half a tube of Benger's is enough!



While half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup, in most cases in 10 minutes, the extent of the peptonising action can be regulated by either increasing or diminishing the quantity of the powders, and by lengthening or shortening the time during which they are allowed to act on the milk, gruel, etc.

Generally speaking, Benger's Peptonising Powders produce the required result with half the quantity necessary of other preparations, whose initial cost also is higher.

Prices:
No. 1 — Box of 6, 1/-; No. 2 — Box of 12, 1/8

Benger's Liquor Pancreaticus.

An important aid in the preparation of Peptonised Milk, etc.

Benger's Liquor Pancreaticus is an active solution of the digestive principles of the Pancreas; a really efficient agent for the digestion of milk, gruel, and farinaceous or partly farinaceous foods. Benger's Liquor Pancreaticus is odourless and tasteless.

In 4, 8 and 16-oz. bottles.

BENGER'S Food

REGD. TRADE MARK.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S
PURE FLUID
MAGNESIA

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Successful in Rheumatic Arthropathies

'Iodolysin' is a chemical compound containing 43 per cent. of Thiosinamin and 47 per cent. of Iodine. It is readily soluble in water, is generally well tolerated and solutions of it do not cause local reaction on injection.

'Iodolysin' is employed as a fibrolytic agent for the removal of all forms of pathological fibrous tissue. The numerous and very favourable reports received from physicians, emphasise its real value in many cases of rheumatism, particularly rheumatoid arthritis and arthritis deformans. Good results have also been reported from the use of 'Iodolysin' in eye infiltrations, such as glaucoma, and it is employed with advantage in strictures of the œsophagus, rectum or urethra, in pyloric stenosis, arterio-sclerosis, Dupuytren's contraction and osteoarthropathies.

'Iodolysin' is supplied in ampoules for hypodermic injection, in the form of capsules for oral administration, or as an ointment for local application.

ORAL SEPSIS.

"EUMENTHOL JUJUBES"

(HUDSON)

Made in Australia.

A Gum pastille containing the active constituents of well-known Antiseptics, Eucalyptus Polybractea (a well-rectified Oil free from aldehydes (especially valeric aldehyde), which make themselves unpleasantly noticeable in crude oils by their tendency to produce coughing), Thymus Vulg., Pinus Sylvestris, Mentha Arv., with Benzo-borate of Sodium, &c., they exhibit the antiseptic properties in a fragrant and efficient form. Non-coagulant antiseptic and prophylactic, reducing sensibility of mucous membrane.

THE LANCET says:—

"In the experiments tried the Jujube proved to be as effective bactericidally as is Creosote."

Mr. W. A. DIXON, F.I.C., F.C.S.,

Public Analyst of Sydney, after making exhaustive tests, says:—

"There is no doubt but that 'Eumenthol' Jujubes have a wonderful effect in the destruction of bacteria and preventing their growth. . . . , I have made a comparative test of 'Eumenthol' Jujubes and Creosote, and find that there is little difference in their bactericidal action."

THE PRACTITIONER says:—

"They are recommended for use in cases of oral sepsis, a condition to which much attention has been called in recent years as a source of gastric troubles and general constitutional disturbance, and are also useful in tonsillitis, pharyngitis, &c."

THE AUSTRALASIAN MEDICAL GAZETTE states:—

"Should prove of great service."

YEAST-VITE TABLETS.

The New Yeast Vitamin Treatment.

We hold high medical testimony showing efficacy in cases of SEPTICÆMIA, PYÆMIA, skin blemishes and other disorders of the blood.

They act with quick stimulating effect on the pancreas, liver and kidneys.

The antipyretic, anodyne and analgesic action is more pronounced than that of the usual coal tar derivatives, without unfavourable reaction, and have the advantage of rapid assimilation.

Of value as a vitaliser and rejuvenator

Recommended as a nerve sedative, and of considerable value in moderating menstrual and labour pains.

We supply (without charge) to physicians, hospitals, clinics and nurses sufficient supplies for exhaustive tests.

Intestinal Disinfection

ALIMENTARY TOXÆMIAS

IN our last advertisement, the subject of Alimentary Toxæmia was briefly discussed, and intestinal disinfection by means of Kerol Capsules was held to be the first line of treatment.

The reason for this may be stated as follows:—None of the ordinary so-called intestinal antiseptics, such as Salol and Beta Naphthol, are found experimentally to exert any disinfection of the contents of the bowel.

On the other hand, the high boiling hydroxyl compounds of the coal tar series are potent germicides, and, being unabsorbed, are non-toxic. They can therefore be administered freely without harm, and are found to prevent the multiplication of the toxæmic intestinal bacteria and to reduce them considerably.

The active principle of Kerol is a complex mixture of these compounds. The administration of two 3-minim capsules thrice daily after meals has been repeatedly shown to reduce the coli content of the stools of individuals taking them by 99 per cent.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

The Doctor's Cocoa

The value of **Schweitzer's COCOATINA** has been recognised by the Medical Profession for over **50** years, and its claims have been endorsed by many of the most eminent authorities on dietetics.

SCHWEITZER'S
COCOATINA

COCOATINA, in addition to its high nutritive value, is rich in theobromine, and is, therefore, valuable as a cardiac stimulant for patients after operation.

COCOATINA is an ideal nutrient in cases of gastric and duodenal ulcer. It is easily digested and occasions no irritation.

THEORIES COME and THEORIES GO!

THIS applies particularly to baby foods. First it's this formula, then it's that formula. Somebody says this, then somebody says that.

In the preparation of Humanised Trufood hypothetical formulæ have been *totally ignored.* We aimed to make a diet that more *closely* approximated to mother's milk than any alternative food available to-day. We have *succeeded;* with the result that Humanised Trufood and breast milk are almost *analogous.*

Samples and literature on request.

ANTIVIRUS.

A specific topical non-toxic application for the cure of localised accessible infections, obtained from media in which the organism has been grown to extinction. It evokes a direct and purely local antibacterial action.

Antivirus, if maintained aseptically, does not lose potency.

STREPTOCOCCUS ANTIVIRUS.

Prepared and stocked in 4 sorts—

1. **Strept. erysipelatis Antivirus** for use in erysipelas.
2. **Strept. pyogenes Antivirus** for use in acute infections with this organism, *e.g.* cellulitis, lymphangitis, wound infections, uterine infections (puerperal).
3. **Strept. salivarius (parodontal, etc.). Antivirus** for use against this type *e.g.* pyorrhœa, tonsillitis and glossitis.
4. **Strept, fæcalis Antivirus** for use in superficial lesions about the anus and genitalia, *e.g.* pruritus ani, anal fissures, etc.

STAPHYLOCOCCUS ANTIVIRUS.

Prepared and stocked in 2 sorts—

1. **Staph. aureus Antivirus** for use against boils, carbuncles, sycosis, impetigo contagiosa, etc.
2. **Staph. albus Antivirus** for use against chronic ulcers, sinuses, seborrhœa.

Bacteriological identification of the organism, when practicable, should precede choice of Antivirus.

Mode of use—

Antivirus may be used as compress, dressing, tampon, plug, spray or drops. It is supplied in rubber capped bottles, containing 20 c.c., 50 c.c. and 100 c.c.

Prepared in the Laboratories of Pathology & Public Health, London, W. 1.

***WHY FAIL** at the **F.R.C.S.** England*
(Primary or Final)?

Enrol now for the Oral and Postal Revision Classes and make sure of success.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Exams. on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S. England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise and up to date and the test questions are carefully selected from those set at previous Examinations so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S." free on application to the Secretary. Also Free Guide to all Medical Exams.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)

Berners Street, Oxford Street, W.1.

NO ENTRANCE FEE TO THOSE JOINING WITHIN 12 MONTHS OF REGISTRATION.

In addition to the ordinary benefits of membership, each Member is now provided with **unlimited indemnity** (subject to the provisions of the Articles of Association) against damages and costs awarded in any case which is undertaken by the Union on his behalf.

Full particulars, and forms of application for membership, can be obtained from the Secretary.

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL.

The WINTER SESSION will Open on Monday, October 3rd.

The HOSPITAL is the largest in England. There are 849 beds, in constant use. Last year: number of in-patients, 18,077; out-patients, 129,247; attendance, 591,467; dental patients, 6,935; major operations, 7,873.

The MEDICAL COLLEGE and DENTAL SCHOOL are essentially modern, with large laboratories equipped with the latest and the most approved appliances. The STAFF is so large as to permit of individual attention being paid to all Students.

MEDICAL UNIT.—A Clinical Unit in Medicine, under the charge of a whole-time Director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research.

RESEARCH FUNDS of approximately £90,000 give unrivalled facilities for Medical Research.

SCHOLARSHIP and PRIZES amounting to £959 are awarded annually.

APPOINTMENTS.—Over 160 Appointments are made annually from Students of the College recently qualified.

SPECIAL COURSES are held for all the University Examinations, for the Primary and Final Fellowship Examination of the Royal College of Surgeons, and for the Membership Examination of the Royal College of Physicians.

HOSPITAL PRACTICE.—Exceptional opportunities are offered to qualified Practitioners wishing to attend the General Practice or the Practice of a Special Department of the Hospital.

A Clubs' Union, an Athletic Ground of over 13 acres, and a **Students' Hostel** promote the recreation, health, and comfort of the Students.

For Prospectus and Particulars apply to the Dean (Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S.), who will be pleased to make arrangements for anyone wishing to see the Medical College and Dental School. Mile End, E.1.

POST-GRADUATE TEACHING. WEST LONDON HOSPITAL

WINTER SESSION commences on MONDAY, 3rd OCTOBER.

At 4.30 P.M. the Dean, SIR HENRY SIMSON, K.C.V.O., will read a paper on "POST-GRADUATE EDUCATION IN OBSTETRICS."

Continuous Instruction in General Medicine and Surgery and in all Special Departments until Xmas. Special Annual Membership terms to General Practitioners.

Prospectus from the DEAN, West London Hospital, Hammersmith, W.6.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL. (UNIVERSITY OF LONDON).

Denmark Hill, S.E. 5.

OPENING OF WINTER SESSION, SEPTEMBER 30, 1927.

Introductory Address at 2.30 P.M. by Professor Sir Berkeley Moynihan, Bt., K.C.M.G., President of the Royal College of Surgeons of England. The Right Hon. the Viscount Hambleden will preside.

The Past and Present Students' Dinner will be held the same evening at 7, for 7.30, at the Criterion Restaurant, Piccadilly, W. 1. (The Secretaries to the Dinner Committee are Dr. Ernest Playfair and Dr. H. A. Richards.) The Chair will be taken by Professor G. F. Still, M.D., LL.D., F.R.C.P.

The Calendar of the School, including that of the School of Dental Surgery, giving information as to Prizes, Entrance and other Scholarships, &c., may be obtained on application to the Dean, H. Willoughby Lyle, M.D. Lond., F.R.C.S., J.P., or to S. C. Ranner, M.A., Cantab., the Secretary of the Medical School.

A RESIDENT MEDICAL OFFICER required 1st November.
HOUSE PHYSICIAN required 1st November.

Applications are invited for these posts. The salaries are at the rate of £150 and £100 per annum respectively, and the appointments are for six months. Candidates for the post of Resident Medical Officer should state if they are willing to take that of House Physician, and applications, accompanied by copies of three recent testimonials, should reach me by 5th October.

The accommodation at the Hospital does not permit of Women Graduates holding these appointments.

H. W. BURLEIGH, Secretary and General Superintendent.

The Belgrave Hospital for Children
(Incorporated), Clapham-road, S.W. 9.

The Committee of Management invite applications for the posts of

HOUSE PHYSICIAN,
ASSISTANT HOUSE PHYSICIAN,
HOUSE SURGEON,

which will become vacant on October 31st. Applicants (Men) must be fully qualified and registered, and in the case of the Senior post they should have held at least one Resident appointment. The appointments are for six months, with board, residence, and washing provided. Salary at the rate of £100 per annum in each case. Applications, with copies of testimonials stating age, to be forwarded on or before Wednesday, October 5th.

By order.
THOS. CLAPHAM, Secretary.

Aberdeen Royal Infirmary.

The Board of Directors invites applications for the following appointment to the Honorary Staff, viz.—JUNIOR ASSISTANT OPHTHALMIC SURGEON.

Each candidate in his application should submit a full statement of qualifications and experience, along with three recent testimonials, and fifteen copies of each should be lodged with the Clerk and Treasurer, Aberdeen Royal Infirmary, 343, Union-street, Aberdeen, not later than Monday, 3rd October, 1927.

Royal Devon and Exeter Hospital,
Exeter. (200 Beds.)

HOUSE PHYSICIAN (Male), vacant 20th October, 1927.

CASUALTY OFFICER (Male), vacant 28th October, 1927.

Applications are invited for these resident posts.

The appointments are for six months but candidates are eligible for re-election.

The salaries are as follows: House Physician £130 per annum, Casualty Officer £100 per annum with board, apartments, and washing.

Applications, giving full particulars as to age, qualifications, together with certificate of registration and copies of recent testimonials, should be sent to the undersigned on or before Wednesday, 5th October, 1927.

By Order of the Committee.

September 16th, 1927. S. S. COLE, Secretary.

Gravesend and North Kent Hospital,
Kent.

JUNIOR HOUSE SURGEON.

Applications are invited from fully qualified men for the above post.

The Hospital contains 72 beds and cots, and has a large Out-Patient, Casualty and Ophthalmic Department.

Owing to the unique situation of the Hospital at the entrance to the Port of London, many accidents and interesting cases are treated, and the post affords an excellent opportunity for surgical experience.

The appointment will date from November 1st, 1927, and will be for twelve months, at a salary of £150 per annum, payable at the rate of £50 for the first six months as Junior House Surgeon, and the second six months as Senior House Surgeon at the rate of £100, in equal monthly instalments. There is also a possibility of the successful applicant being retained for a further six months, as a Resident Medical Officer at the rate of £250 per annum.

Applications, with copies of three recent testimonials, should be sent to the undersigned not later than the 15th of October, 1927. C. E. CHAPMAN, Secretary.

September 16th, 1927.

Warwickshire and Coventry Joint
COMMITTEE FOR TUBERCULOSIS.

ASSISTANT TUBERCULOSIS OFFICER.

Applications are invited from qualified and registered Medical Practitioners for the post of Assistant Tuberculosis Officer. Applicants must be prepared to devote the whole of their time to the duties of the office, and must have had special practical experience in the treatment of Tuberculosis in Sanatoria, Dispensaries and otherwise, and must be thoroughly acquainted with modern methods of diagnosis and treatment.

The salary is at the rate of £650 per annum, and is subject to a deduction of 5 per cent. in respect of contributions under the Local Government and Other Officers' Superannuation Act, 1922; in addition, motor-car allowances in accordance with the Committee's scale and reasonable travelling expenses are paid. The appointment is also subject to a satisfactory medical examination by one of the Committee's independent Medical Referees.

Forms of application, and statement of the duties and terms of the appointment, can be obtained from the undersigned. Applications marked "Assistant Tuberculosis Officer," with copies of not more than three recent testimonials, must be received by me not later than the 15th October, 1927.

Canvassing directly or indirectly will be considered a disqualification.

L. EDGAR STEPHENS, Clerk of the Joint Committee.

42, Warwick-street, Leamington, 15th September, 1927.

City of Leeds.

ASSISTANT CLINICAL TUBERCULOSIS OFFICER.

Applications are invited for the post of Assistant Clinical Tuberculosis Officer. Applicants should be duly qualified and registered Medical Practitioners, and must have had not less than three years' post-graduate experience, including experience in General Medicine and Surgery, and in the treatment of Tuberculosis in a Hospital, Sanatorium or other institution reserved for such cases. The possession of a D.P.H., though not essential, would be considered an additional qualification. The salary will be £600 per annum.

The person appointed will be required to undergo a medical examination, and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922. He or she will also be required to enter into an agreement of service with the Corporation, terminable by one month's notice on either side. Form of application may be obtained from the Medical Officer of Health, 12, Market Buildings, Vicar-lane, Leeds.

Applications, endorsed "Tuberculosis Officer," together with copies of not more than three recent testimonials, must be delivered at my office, 26, Great George-street, Leeds, not later than Wednesday, 28th September, 1927.

Leeds, Sept. 9th, 1927. THOS. THORNTON, Town Clerk.

Liverpool School of Tropical Medicine.

Two RESEARCH ASSISTANTS required for the School Laboratory at Freetown, Sierra Leone. Salary £600 per annum, furnished quarters provided; leave granted at the end of each year. Successful candidates will be required to take a preliminary course of instruction at the School in Liverpool. Applications should be received not later than 30th September. For further particulars apply to the Hon. Dean, School of Tropical Medicine, Pembroke-place, Liverpool.

Royal Salop Infirmary, Shrewsbury.

—The Board of Management is prepared to consider applications from suitable candidates for the position of SECRETARY-SUPERINTENDENT. He must have had administrative experience and possess a thorough knowledge of Accounts.

Salary £600 per annum.

Applications stating age, experience, and not more than three recent testimonials, must be received not later than October 15th, addressed to the Chairman of the Board of Management, Royal Salop Infirmary, Shrewsbury.

Personal canvassing will disqualify.

Jersey General Hospital and Poor
LAW INFIRMARY.

RESIDENT MEDICAL OFFICER.

Applications are invited for the above post (male). Applicants must be duly qualified practitioners in medicine and surgery. Salary £200 per annum, with board, residence in the hospital, and laundry.

The appointment is for one year, and is renewable. Applications, with testimonials, must be sent in on or before Saturday, October 1st, 1927, addressed to the undersigned, from whom further particulars may be obtained.

P. BEUZEVAL, Secretary.

West Derby Union.

RESIDENT ASSISTANT MEDICAL OFFICERS (MALE).

The Guardians invite applications for the above Appointments at the MILL ROAD INFIRMARY and the SMITHDOWN ROAD INSTITUTION, Liverpool, respectively, at salaries after the rate of £200 per annum, together with the usual resident allowances.

Candidates must be single, fully qualified and registered.

Appointment will be for a period of one year in the first instance, subject to one month's notice to terminate on either side at any time, and to extension for a further period of twelve months at the option of the Guardians.

Applications, stating whether willing to accept either of the positions, giving age, qualifications, &c., with copies of three recent testimonials, to be sent to the undersigned not later than Tuesday, 4th October, 1927.

G. W. COSTER, Clerk to the Guardians.

Union Offices, Brougham-terrace, Liverpool.

14th September, 1927.

County Borough of Smethwick.

LADY ASSISTANT MEDICAL OFFICER.

The Council invite applications for the combined office of Lady Assistant Medical Officer of Health and School Medical Officer.

The duties will include attendance at the Maternity and Infant Welfare Centres, Supervision of Midwives, Medical Inspection of School Children (chiefly girls), and supervision of Health Visitors.

The Officer appointed will also be required to assist the Medical Officer of Health in other duties from time to time as directed.

Applicants must be registered Medical Practitioners and possess the Diploma of Public Health. Preference will be given to candidates who have had experience in the Medical Inspection of School Children and Infant Welfare Work.

Salary £600 per annum.

The successful candidate (who will be appointed subject to her passing a medical examination) will be required to contribute to the Corporation's Superannuation Scheme under the Local Government and Other Officers' Superannuation Act, 1922.

Forms of application may be obtained from the undersigned, to whom applications, endorsed "Assistant M.O.H.," and accompanied by copies of three recent testimonials, must be delivered not later than 28th September, 1927.

Canvassing, directly or indirectly, will disqualify.

HUGH PAUL, Medical Officer of Health.

Public Health Department, 280, High Street, Smethwick.

14th September 1927.

FRANK ROWE, Secretary.

Royal Albert Hospital, Devonport, 19th Sept., 1927.

UNITED SERVICES FUND.

Heatherwood Hospital, Ascot.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from fully qualified Medical Practitioners (Bachelors not over 30) for the above post.

Candidates must have held some appointment in a General Hospital.

The present Hospital accommodation is 136 beds for the treatment of Surgical Tuberculosis and other forms of crippledom.

The appointment will be for a period of twelve months and may be extended at the end of that time.

Remuneration is at the rate of £300 per annum, together with residence, board, and laundry.

The officer appointed will be required to devote the whole of his time to the duties of the office, to give anæsthetics, etc., and generally to act under the supervision and direction of the Medical Superintendent.

Applications, stating (1) age, (2) qualifications, (3) experience and appointments held, accompanied by three copies of recent testimonials, should be forwarded to the Secretary, Heatherwood Committee, United Services Fund, 29, Cromwell-road, South Kensington, London, S.W. 7, before 3rd October, 1927.

Further particulars can be supplied on application to the Medical Superintendent, Heatherwood Hospital, Ascot, Berks.

North Staffordshire Royal Infirmary,

Hartshill, Stoke-on-Trent.

VACANCY FOR AN HONORARY ASSISTANT OPHTHALMIC SURGEON.

The Committee invite applications for the post of Honorary Assistant Ophthalmic Surgeon.

Candidates for appointments to the Honorary Medical Staff of the Infirmary will be required to produce evidence that they hold the Degree of Doctor of Medicine of a British or Irish University; the Degree of Master in Surgery of a British or Irish University; the Diploma of Fellow of one of the Royal Colleges of Surgeons of Great Britain or Ireland, or the Diploma in Ophthalmology.

Candidates will also be required to produce satisfactory evidence of having (after becoming qualified) filled an Ophthalmic appointment in a Hospital specially devoted to Eye work, or an appointment in the Ophthalmic Department of a recognised Medical School.

All the Members of the Honorary Medical and Surgical Staff must reside within five miles of the North Staffordshire Royal Infirmary, and must be communicable by telephone.

Candidates will be required to attend before the Election Committee at this Infirmary on Thursday, 13th October, at 3 P.M.

Canvassing will disqualify.

No testimonials will be permitted, but a candidate will be allowed to send to each member of the Election Committee a copy of his application, in which will be stated his age, qualifications, and experience.

A list giving the names and addresses of the members of the Election Committee may be obtained from the undersigned, in whose hands applications for the post of Honorary Assistant Ophthalmic Surgeon must be (with proof of the necessary qualifications) on or before Monday, 10th October, 1927.

By Order of the Committee,

W. STEVENSON, Secretary and House Governor.

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES,
who have both had many years' experience as Medical Transfer Agents.

An Accountant's Certified Report is required in respect of every Practice or Partnership the disposal of which is undertaken by the Agency.

The commission chargeable in respect of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

NO CHARGE IS MADE TO PRINCIPALS FOR THE INTRODUCTION OF LOCUM TENENS OR ASSISTANTS.
Accountancy and Legal Services furnished by the Agency, where desired, at moderate inclusive charges.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. HAMPSHIRE.—PARTNERSHIP.—A One-third or One-fourth Share is for disposal (after preliminary assistantship) in a well-estab. non-dispensing Practice, situated in a small Town near Coast. Receipts for past 12 months over £2700 and increasing. Fees 3s. 6d. to 30s. Not much Midwifery. Suitable house can be bought. Premium 2 years' purchase.
2. NORTH CORNWALL.—Well-estab. Mixed General PRACTICE, situated in popular Coast Town. Receipts for past year over £4100 and increasing. Fees from 5s. to 2 gns. Panel of 500. Very well suited for 2 friends in partnership, as 2 houses available, which can be rented at £100 and £90 p.a. respectively. If preferred a one-half share will be sold. Premium 2 years' purchase.
3. LONDON, EAST.—PARTNERSHIP.—Owing to the death of the senior partner, a Half Share is for disposal in an old-estab. middle- and working-class Practice, averaging £2532 for the past 3 years. Fees from 2s. 6d. to 10s. 6d. Suitable and commodious house with large garden can be rented on lease at £75 p.a. Good scope for increase. Premium £2500, part by instalments.
4. WESTERN SUBURB.—Old-estab. Mixed-class PRACTICE (with good sprinkling of better class), averaging nearly £1000 p.a., including panel over 800. Visits from 3s. 6d. to 10s. 6d. Very little Midwifery. Car not required. Good corner house in excellent position and containing ample accommodation for family, with large garden, separate entrance to surgery, etc. Price £1400, part on mortgage. Premium 1½ years' purchase. Ill-health reason for disposal.
5. NORTH WALES.—Pleasant Coast Town.—PARTNERSHIP.—A One-third Share (after preliminary Assistantship of 6 months) in an old-estab. Mixed General Practice. Average income approximately £4500, including panel of 1500. Fees 3s. 6d. to 21s. Little Midwifery. Choice of houses. Premium 2 years' purchase.
6. NORTH LONDON.—Old-estab. Middle and Working-class PRACTICE. Average income about £900. Panel of 800. Advice and medicine 2s. and 2s. 6d. Visits 3s. 6d. and 4s. 6d. No Midwifery. Small convenient house; rent £53 p.a. Large scope for increase. Premium £1300.
7. ITALY.—SEASON PRACTICE.—High-class Practice for disposal, owing ill-health. Income about £350, but much scope. Fees from 21s. Premium £500.
8. SHROPSHIRE.—PARTNERSHIP.—In a pleasant Market Town amidst beautiful surroundings, the Half Share of a very old-establ. Practice, averaging over £3600 p.a., including appts. and panel of 2500, is for disposal in consequence of the retirement of the senior partner. Visits 5s. to 2 gns. Mid. 3 to 5 gns.; 40 to 50 cases yearly. Good house with ample accommodation; rent on lease £65 p.a. Small Hospital and scope for surgery if desired. Premium 2 years' purchase. Sport, etc.
9. NORFOLK.—Small Town, within easy access of Coast.—Old-established mixed-class PRACTICE, averaging for last 3 years £1347 (last year nearly £1400), including panel of 850. Fees from 2s. 6d. to 21s. Good house with 2 reception, 7 bedrooms, etc., and usual professional accommodation, garden with tennis-court. Price for freehold £2100—£1000 on mortgage. Hunting, shooting, etc., and excellent schools within reach. Premium £2000.
10. SOUTH DEVON.—Pleasant small Town, within easy access of Sea. Old-estab. mixed, mainly middle- and upper-class PRACTICE. Average income for the last 3 years over £2000, including panel of 600. Fees 5s. to 21s., with a few at 3s. 6d. cash. Exceptionally good house, with ample accommodation and ½ acre of garden. Electric light, etc. Excellent sport, schools, and social life. Premium for house and practice, £5000.
11. LONDON, NORTH-WEST.—Old-estab. Middle- and Working-class PRACTICE, averaging for the past three years over £1900. Panel of 400, but ample scope for this, as only recently started. Fees from 2s. 6d. to 10s. 6d. House contains 1 reception, 3 bedrooms, bathroom, &c., surgery, waiting-room, and dispensary. Can be rented on lease at £80 p.a. Premium 1½ years' purchase.
12. SUSSEX.—Favourite Residential Town.—PRACTICE in an old-estab., chiefly better-class one, held by Vendor over 20 years. Income for the past 12 months over £2100. Panel of 1020. Fees from 2s. 6d. to 15s. Very good detached house, with 2 reception, 4 bedrooms and dressing-room, and 2 servants' rooms, &c. Large garden. Price for freehold £3000. Premium £3000.
13. WITHIN FIFTY MILES OF LONDON.—Exceptionally attractive residential district. Old-estab. chiefly better class Practice. Income for the past year about £2500 and increasing. Panel of 900. Fees 4s. to 21s. Not much Midwifery at from 4 gns. Very good house, in excellent repair, having ample accommodation and large garden. Can be rented on lease at £150 p.a. First-rate sporting, social and educational facilities. Good surgical scope. Premium £4500.
14. LONDON, NORTH.—Old-estab. middle-class PRACTICE, capable of great extension. Present income about £350, including panel of 205. Fees from 3s. 6d. upwards. Midwifery has been refused. Large corner house with ample accommodation. Price for leasehold £1100, or would be let on lease at £75 p.a. Premium £400.
15. SOMERSET COAST.—In a very pleasant Seaside Resort, a SHARE, from one-sixth to one-fourth, is for disposal in an old-estab. middle- and better-class Practice, worth over £4600 p.a., including panel of 1800 and appts. of £200. Visits up to 15s. Very little Midwifery. Suitable house can be bought, or purchaser (if single) can reside in rooms. Premium 2 years' purchase.
16. HOME COUNTIES.—Unopposed Country PRACTICE in first-class residential district within 3 miles of favourite town. Income £900 to £1000 p.a., including union and panel over 550. Visits 3s. 6d. to 21s. Practically no Midwifery. Excellent family residence (3 reception, 5 or 6 bedrooms, 2 bathrooms, &c.), with good garden. Water and electric light. Price freehold £2300. Premium £1500. Educational facilities and sport.
17. SOUTH AFRICA.—In a small rapidly growing Town, in prosperous and rich agricultural and pastoral district, nearly 5000 ft. above sea level, delightful climate, dry and healthy, a well-estab. PRACTICE, producing last year over £1900, including appt. worth £80. Visits 5s. to 10s. (medicine extra) in the town, mileage extra outside. Midwifery 5 to 10 gns.: about 25 cases p.a., 8-roomed house, with bathroom, &c., on long lease; rent £72. Good sanitation and water-supply. Educational facilities and sport of all kinds. Premium £1000, to include drugs, bottles, &c.
18. NORTH MIDLANDS.—Pleasant Town.—PARTNERSHIP. A 1/3 Share to commence with, in an old-estab. Mixed General Practice, including county families. Income for last year over £3000, including panel of about 1250. Fees 3s. 6d. to 21s. Little Midwifery. Small but convenient house, with garden. Price £850. Good golf. Prem. £1500.
19. PARTNERSHIP.—Hospital Town in South-West of England —The Half Share of an old-estab. mixed class PRACTICE averaging over £4600 p.a., including panel and appts. Visits 5s. to 21s., medicine extra. No Midwifery. Suitable residence available. Rent on lease under £50 p.a. Ingoing partner should be keen on surgery, well qualified and about 30 years of age. Premium 2 years' purchase, half down and balance by easy instalments. Sport and educational facilities, &c.
20. WELSH HOSPITAL TOWN.—Old-estab. mainly good-class non-dispensing PRACTICE. Income over £1400, including about £130 from appointments, and panel of 500. Fees from 5s. to 2 gns. Not much Midwifery. Good house, with 2 reception, and 4 bedrooms, etc. Large garden. Price for freehold £1500. Premium 1½ years' purchase.
21. SURREY.—Riverside Town.—PARTNERSHIP.—A One-third Share to commence with in an old-estab. non-dispensing and non-panel Practice. Average income £1626, with scope for increase, and surgical work. Fees 5s. to 21s. Suitable house can be bought. Premium 2 years' purchase. Purchaser should be experienced, and not over 35 years of age.

Profits accruing to Bovril, Ltd., from the Agency are allocated amongst recognised Medical Charities.

Full Schedule of Terms and Conditions will be forwarded on application.

'KEPLER'
Cod Liver Oil
tested for
Vitamin D content

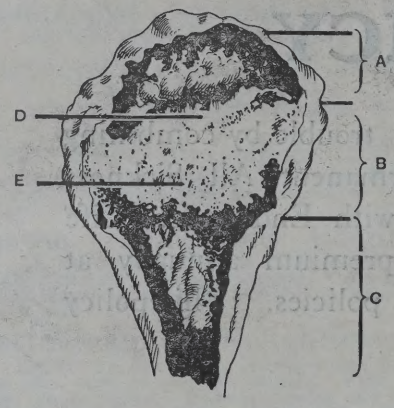

Fig 1

Femur of rat fed on rickets-producing diet deficient in Vitamin D.

A—Epiphysis.
B—Metaphysis.
C—Diaphysis.
D—Epiphyseal-diaphyseal cartilage.
E—Osteoid tissue

There is no calcification of the provisional zone of cartilage. A wide rachitic metaphysis absent from normal bone is formed

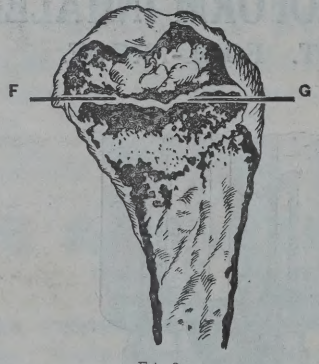

Fig 2

F—Epiphyseal-diaphyseal cartilage.
G—Calcification of provisional zone of cartilage.

Femur of rat fed for the same time as Fig. 1 on the same rickets-producing diet, but with the addition during the last three weeks of 0·01 c.c. of 'KEPLER' Cod Liver Oil each day. Healing is commencing and normal calcification of the provisional zone of cartilage is taking place, demonstrating the high Vitamin D content of 'KEPLER' Cod Liver Oil.

Diseases due to Vitamin deficiency

Very few such diseases are due entirely to the lack of one single vitamin. This is illustrated in the case of rickets by the important subsidiary part played by a shortage of Vitamin A.

It is the Vitamin A and D content of the cod liver oil, combined with the Vitamin B content of the malt extract, which gives unique value as a complete dietary adjunct to

TRADE **'KEPLER'** MARK

Cod Liver Oil

with

Malt Extract

There is no well-attested substitute for cod liver oil as a means of securing a full vitamin content in the diet.

'Kepler' Cod Liver Oil has been specially selected for its vitamin content since the year 1923.

Supplied to the Medical Profession, in bottles of two sizes, at **2/6** *and* **4/7** *each*

Full particulars and prices of 'Kepler' combinations will be found in WELLCOME'S MEDICAL DIARY
